I. Introduction

Ever higher demands are being made on bearing systems, and a variety of techniques and new materials have been developed that are designed to meet the needs of today's demanding and extremely varied technical and commercial applications.

IBC Wälzlager GmbH, Industrial Bearings and Components, rises to the challenge by constantly enhancing its performance, continuously optimising its products and processes and by expanding its product range.

Together with our customers, we define objectives and consistently pursue our common objectives. And by keeping our communication channels with the customer open at all times, even very specific customer requirements are swiftly and purposefully converted into commercial solutions.

We have also been traditionally involved in academic work: We are in close working partnerships with colleges and universities, both in the field of research and development and as our point of reference for vocational training.

Our capability to innovate can be seen in our intense research and development efforts. Basic research, material engineering, tribology and bearing design, and the improvement of manufacturing processes make up our main areas of research and development. The use of different types of materials for bearing components, for instance, is one of the decisive factors in increasing the performance of the products.

Apart from its use in research and development, our modern equipment also forms the foundation which enables us, together with our skilled staff, to produce rolling bearings to the highest quality specifications. It also ensures our quality in the long term. And because we use such sophisticated machinery, we pay special attention to the people who are part of the process.

Although ceramic rolling elements were initially used only in specialised applications, they are now part of the standard programme of high precision bearings. They are used in the machine tool manufacturing sector or in electric motor engineering,

for instance. Enhanced cage materials like PEEK are used for fast-running high precision bearings or in a high temperature environment.

High precision bearings that are grease-lubricated in our factory and additionally sealed are maintenance-free, meaning that "for life lubrication" becomes a reality. This fact contributes both to simpler, customer-friendly designs and to simpler assembly.

IBC Wälzlager's product range is further expanded by ATCoat thin dense chromium coated bearings that are designed for specialised applications. The advantages of high precision bearings coated with ATCoat include service-life boosting characteristics as well as outstanding wear and corrosion protection properties.

In this publication you will find a whole variety of products, as well as variations in each product. The products showcased here include high precision angular contact ball bearings and high precision cylindrical roller bearings for machine tool manufacturers, the printing-press and textiles machinery industries and for all applications where extremely high requirements exist with regard to running accuracy, reliability, high rotational speeds, low-friction and quiet running, stiffness, load, heat generation and the given installation conditions, either as single requirement or as combination of above.

The overview of IBC's range of high precision bearings is further supplemented by criteria for choosing a suitable bearing and its appropriate dimensioning; also included are criteria that will help you to design your bearing application and to mount the rolling bearings.

IBC high precision angular contact ball bearings can be supplied with a variety of contact angles, various rolling element diameters and rolling elements made of steel or ceramics and either sealed or open. The bearing you choose will depend on the intended application. You may also choose a variant that offers direct lubrication via the outer ring. This range of options will

help you select the right bearing for a specific application, depending on the requirements you have for speed, load rating, stiffness, feasibility of lubrication and other ambient parameters. The product portfolio of IBC Wälzlager GmbH contains diverse and innovative solutions that ensure that both locating and floating bearings function in a secure way. We offer both high precision angular contact ball bearings with a structural locating bearing function and high precision cylindrical roller bearings with a floating bearing function. As an alternative, you may choose bearing rings coated with ATCoat that prevent fretting corrosion and ensure sliding fit.

Other components of bearing systems, like locknuts or labyrinth seals, have been a fixture of IBC Wälzlager's product range for many years now. They are used for the bearings of ball screws, for example. The many different variations that exist for a certain product help the user to optimise his economic efficiency.

Continuous quality control, which is built into our manufacturing process, and our commitment to, and responsibility towards, compliance with safety and environmental aspects guarantee the

consistently high quality of our products. Our efficient quality management system has been implemented and certified pursuant to DIN EN ISO 9001 for the engineering, design, development, manufacture and sale of rolling bearings and linear guides.

In-depth information on the various rolling bearing designs, and on choosing the right bearing and securely integrating it into the individual design, is to be found in our separate product catalogues that each focus on a specific design.

Our comprehensive product range and the ability to support our customers on-site all over the world via our service and technical departments enable us, to develop specific and efficient bearing solutions for our customers, and together with our customers.

2. IBC High Precision Angular Contact Ball Bearings

2. IBC High precision angular contact ball bearings

IBC high precision angular contact ball bearings have been designed for all rolling bearing applications that make great demands on reliability, stiffness, speed capability and running accuracy; either as a single requirement or as a combination of the above. The many different types available allow spindle manufacturers across different sectors of industry as well as special-purpose mechanical engineering firms to optimise their spindles by focusing on the aspects that are most important to them. Technology and economic efficiency thus meet to form a winning combination.

In order to achieve both improved performance and reduced costs for rolling bearings, the many application-specific requirements for running accuracy, load carrying capacity, rotational capacity, stiffness, vibration characteristics and installation space call for a whole variety of bearing series, each providing different solutions and dimensions that have different design characteristics.

Dimensional series

The IBC product range contains many different variations of single-row high precision angular contact ball bearings.

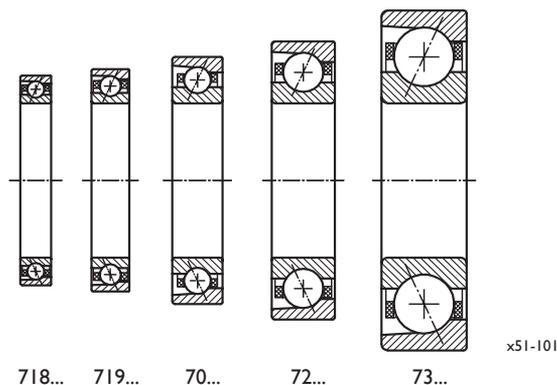

Fig. 2.1: Dimensional series for IBC high precision angular contact ball bearings

According to the German standard DIN 616 each type is assigned a dimensional series that consists of a diameter series and a width series. The dimensional series defines the outside diameter D , the bearing width B and the corner radii r . The identification number for the dimensional series is prefixed by the code "7", which stands for "angular contact ball bearing".

Each dimensional series has special characteristics that make it suited to certain types of rolling bearings.

Dimensional series 18 is the series with the smallest cross-section for high precision angular contact ball bearings; this series is designed for the highest speeds with simultaneously low requirements for load carrying capacity. There is an increase in overall width and outside diameter with dimensional series 19, 10 and so on.

Dimensional series 19 and 10 are used for higher speeds or small radial cross-sections, whereas dimensional series 02 and 03 are used for high loads with relatively low speeds. If great demands are made on the stiffness of rolling bearings, it is usually best to choose

high precision angular contact ball bearings from dimensional series 19, as these have the greatest possible number of rolling elements and allow for large shaft diameters with a given outside diameter.

Contact angle

The contact angle is defined as the angle between an imaginary straight line joining the points of contact of the rolling elements with the raceways and a line perpendicular to the rotational axis.

IBC has tailored the internal design of its high precision angular contact ball bearings to the diverse requirements of the machine tool building industry. IBC therefore offers as standard high precision angular contact ball bearings with three different contact angles. Each dimensional series is designed with a contact angle of 15°, 25° or 30°. The high-speed angular contact ball bearings (H and CBH design) have a contact angle of 18°.

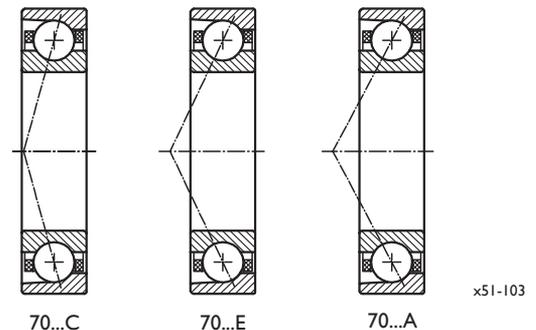

Fig. 2.2: Contact angles for IBC high precision angular contact ball bearings

The different contact angles meet individual requirements for combined loads with regard to stiffness and rotational speed characteristics. IBC also manufactures precision angular contact ball bearings with contact angles of 35°, 40° and 60°. You will find information on these bearings in the publications **Angular Contact Ball Bearings 40° TI-I-4044** and **Ball Screw Support Bearings TI-I-5010**.

Designs

As variants to the standard design, angular contact ball bearings can be supplied with smaller or ceramic rolling elements in order to achieve higher speeds.

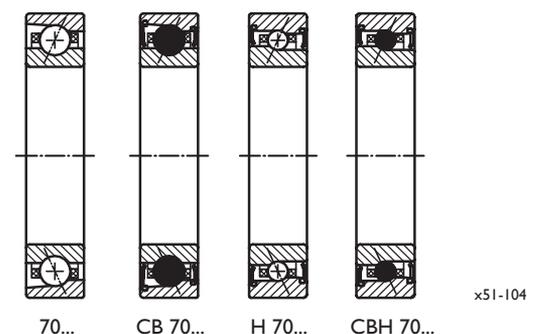

Fig. 2.3: The standard, CB, H and CBH design from the same dimensional series

So-called hybrid bearings retain the original bearing geometry but are equipped with ceramic rolling elements. The high-speed H design utilises smaller rolling elements within an unchanged outer geometry; the CBH design combines both smaller **and** ceramic rolling elements. The CBH design is suitable for the highest speeds, but does not have such a high load carrying capacity.

Hybrid bearings equipped with ceramic rolling elements and rings made of bearing steel are used not only in high-speed applications; their many advantages also include their reliability and their extended grease service life. The combination of harder and lighter ceramic rolling elements reduces the rolling bearing's heat output and the wear of the lubricant. They also improve rolling conditions in an unfavourable lubrication environment and provide insulation to prevent electrical current flowing through the bearing. This leads to greatly reduced system costs.

IBC Wälzlager GmbH has also made wide-ranging additions to dimensional series 19 and 10 supplementing them with an optimised generation of rolling bearings with the suffix X (CX and EX). As can be seen, this variation is identified as an extension to the contact angle designation. The purpose of this design is to close the gap between the standard and high speed series, by providing bearings that are closely matched and controlled. This new design is characterised by low frictional torque, leading to significantly reduced heat emission, as a result of design techniques applied to the inner bearing geometry.

Sealed IBC high precision angular contact ball bearings

As a result of the increasing demand for grease-lubricated high precision angular contact ball bearings, IBC have extended their range of sealed high precision angular contact ball bearings that are greased ready for use. The standard lubrication fill, implemented during the manufacturing process, ensures the optimal grease type and quantity are applied, which has a positive effect on bearing life and machine performance. IBC high precision angular contact ball bearings are filled with suitable high-performance grease as standard that covers a wide range of operating temperatures. The bearings are ready for immediate installation and operation, subject to normal grease running-in procedure. Further information on this topic can be found in Chapter 7 (Lubrication).

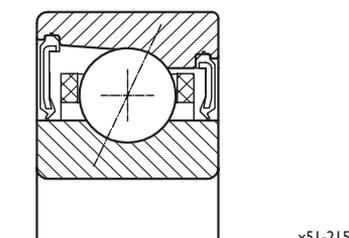

Fig. 2.4: Sealed on both sides with non-contact seals

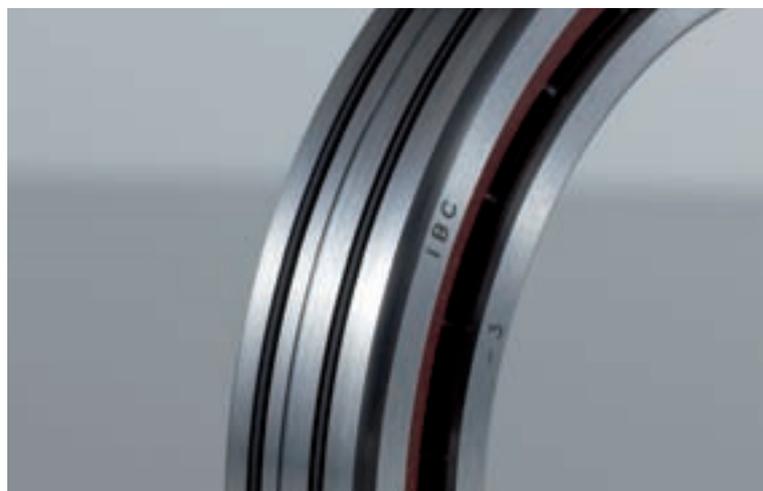

The high precision angular contact ball bearings are ideally protected against contamination and air currents due to being sealed with non-contact seals (2RSZ) on both sides. These seals do not limit the suitability of the bearings for high rotational speeds, and in the case of vertical or pivoting spindles the seals additionally act as grease retention washers. The rolling bearings from dimensional series 18 and 19 as well as H execution bearings come with a standard lubrication fill of GS36 grease; all other bearings come with a standard lubrication fill of GS75 lubricant. There is no special marking for the standard lubrication.

The permitted operating temperature of these seals, which are made of oil-resistant and wear-resistant acrylonitrile butadiene caoutchouc (NBR) and are supported by a reinforced steel plate to provide rigidity, lies between -40° and 120°C.

Oil/air lubrication

Oil/air-lubricated high precision angular contact ball bearings are axially supplied with an oil/air-mixture via intermediate rings. The reference circle for the required lubrication input is detailed in the dimension tables. No changes need to be made to the design of the rolling bearings themselves.

Special designs

Should grease-lubricated high precision angular contact ball bearings be required to run at or above their limits, IBC high precision angular contact ball bearings with outer ring lubrication are an ideal option.

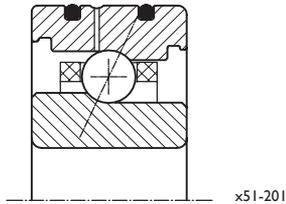

Fig. 2.5: IBC high precision angular contact ball bearing lubricated via the outer ring

A circular groove and a radial supply hole permit direct lubrication. O-rings integrated into the outer ring act as a seal for the housing. The dimensions of the grooves and recesses are contained in Chapter 7 (Lubrication).

High precision angular contact ball bearings with outer-ring lubrication reduce the number of elements that are part of structure around the bearing, leading to savings in installation space and cost reduction.

Apart from the designs mentioned, IBC also produces a number of specially designed high precision rolling bearing variations. Should you be interested in such a design, please contact our technical customer support teams. We will be glad to help you find a solution to meet your specific bearing requirements.

Bearing materials

Rolling bearing rings and rolling elements are generally manufactured from vacuum degassed bearing steel 100Cr6 (1.3505). Ceramic rolling elements are also available in the ceramic material silicon nitride Si_3N_4 . A detailed description of materials can be found in Chapter 9 (Materials).

Heat treatment

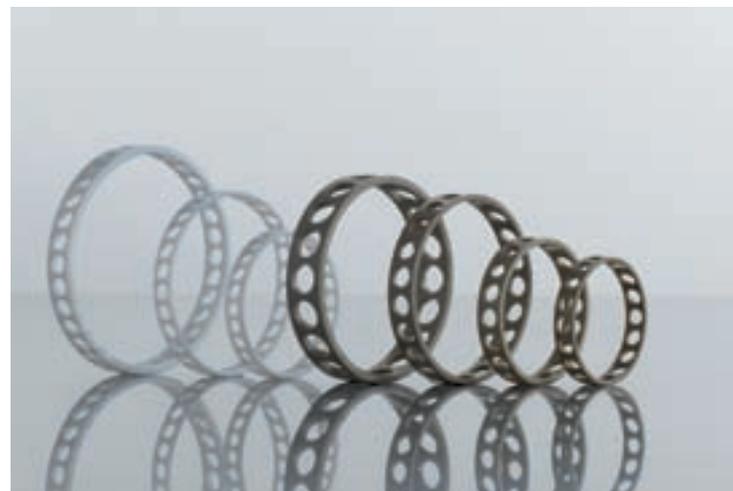

The bearing rings are, as standard, stabilised up to a service temperature of 150 °C. Higher-quality heat treatment is available upon request for higher temperatures. More detailed explanations on this, e.g. types of treatment, restrictions and suitability, are contained in Chapter 9 (Materials).

Cages

As standard, IBC high precision angular contact ball bearings are equipped with a fabric reinforced phenolic resin cage that already meets the requirements of many types of application.

If the high precision angular contact ball bearing is subject to special operating conditions, like high temperatures or extreme accelerations, we provide suitable cages made of alternative materials. Please contact us if your application needs a special type of cage.

A detailed description of the individual cage materials is included in Chapter 9 (Materials).

Bearings with ATCoat coating

In addition to the executions already mentioned, IBC also manufactures high precision bearings with an ATCoat thin dense chromium coating.

You will find a more detailed description of the ATCoat coating in Chapter 10 (IBC High precision rolling bearings with ATCoat coating) and particularly in the publication **ATC Technology Coatings**.

Special mention should be made of the ATCoat thin dense chromium coating of the outer ring in the case of a high precision angular contact ball bearing that is used as a floating bearing. In this case the coating prevents fretting corrosion if the outer ring of the high precision bearing requires a fit that is not too tight, to allow for axial displacement.

2.1 Designation system

IBC High precision angular contact ball bearings

Examples:

CB H 719 14 .E .T .2RSZ .P4A. X2. UL
 X- 70 00 .E .T .P4A. X5. UL

Material

- 100Cr6 rolling elements and rings
- CB** Si₃N₄ rolling elements
- AC-** ATCoat rings
- ACC-** ATCoat rings + Si₃N₄ rolling elements
- X-** ChromoTec rings

Design

- normal design
- H** high-speed design

Dimensional series

718... 719...
 70... 72... 73...

Bore code

00 10 mm 02 15 mm
 01 12 mm 03 17 mm
 from bore code 04: 4 x 5 = 20 mm

Contact angle

- C** 15° contact angle
- E** 25° contact angle
- A** 30° contact angle

Lubrication groove and bore

- standard lubrication facility
- S** re-lubrication facility via outer ring

Cage

- pocket cages, guided on outer ring
- T** fabric reinforced phenolic resin
- M** brass
- K** PEEK
- S** high-grade steel
- PX** polyamide fibre-glass reinforced
- G** PTFE

Seal

- open bearing
- 2RSZ** non-contact seals on both sides

Lubrication

- only corrosion protected or, for sealed bearings, standard GS36 or GS75 grease
- G...** specified grease

ATCoat coating

- no coating
- A11** coated inner and outer ring
- A15** coated inner and outer ring, corrosion resistant rolling elements and cage
- A21** coated inner ring
- A31** coated outer ring

Preload universally faced bearings

- UX** extra light
- UL** light
- UM** medium
- UH** high
- U...** special preload in daN
- A...** axial clearance actual value specified in µm

Angular contact ball bearing sets

- single bearing
- D...** duplex set
- T...** triplex set
- Q...** quadruplex set
- P...** pentaplex set see Chapter 2.7 (Angular contact ball bearing sets)

Sorting, restricted tolerances

- no sorting
- X1, X3, X5, X6, X8** sorting of restricted tolerances for tolerance zone ≤ 5 µm
- X1 to X9** sorting of restricted tolerances for tolerance zone > 5 µm see Chapter 4 (Tolerances)

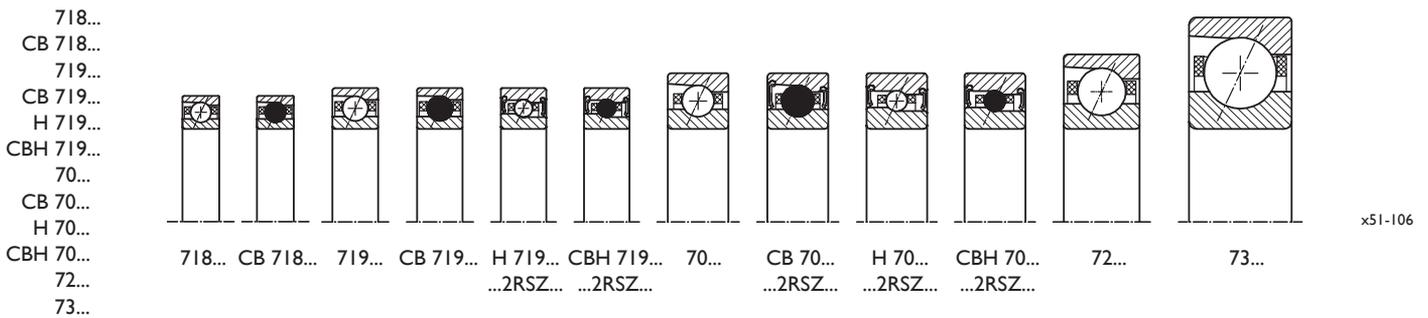

Accuracy

- P4** high accuracy
- P4A** higher accuracy
- P2H** higher accuracy
- P2A** highest accuracy

2.4 Preload and stiffness

A machine tool is seldom a single purpose machine. Based on this a spindle can not be sized to meet a single set of boundary conditions. Eventually sizing a machine tool spindle is based on the total range of the basic application of the machine. If the machine is a multipurpose machine each critical operational condition needs to be calculated.

If high precision angular contact ball bearings are mounted in sets, the ground-in preload essentially determines the characteristics of speed, heat and stiffness. However, high rotational speed and great stiffness are contradictory characteristics. So the best possible compromise needs to be considered.

There have been examples where extremely sophisticated bearings have been designed with elaborate hydraulic devices to create variable preloads

In order to meet diverse requirements, the high precision angular contact ball bearings have therefore been developed not only with different-sized rolling elements, and thus different load ratings, but also with different preloads.

The default preloads have been designated as X for extra light, L for light, M for medium, and H for high preloads. This grading is suitable for the great majority of applications.

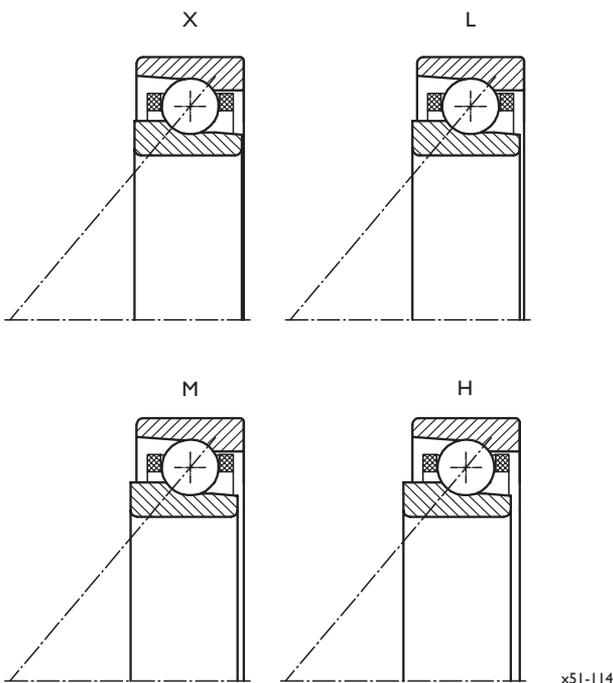

Fig. 2.6: Preload of IBC high precision angular contact ball bearings

The preload of a high precision angular contact ball bearing is defined as the axial force that needs to be applied in order to

align the faces of inner and outer rings; the rings are slightly offset against each other when the single bearing is in an unloaded state. The bearing thereby becomes elastically deformed without, however, sustaining damage.

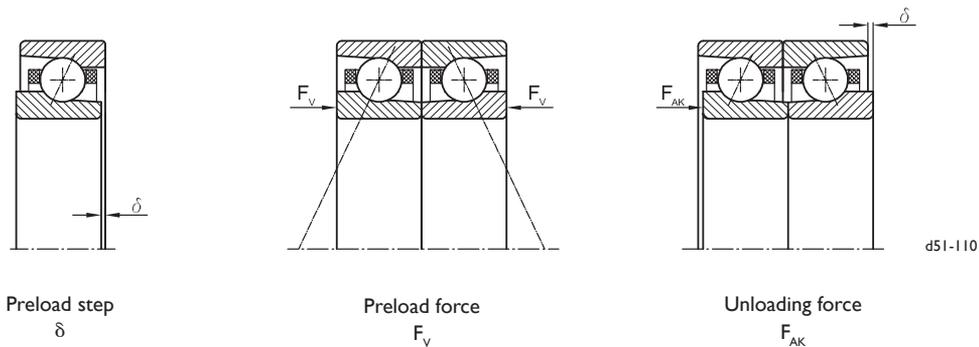

The reciprocal of bearing elasticity is stiffness. Stiffness indicates the resisting force of a preloaded bearing in newtons over its spring deflection in μm . Preload and stiffness are interdependent. As a rule, the stiffness of a bearing does not increase in a linear fashion in relationship to the preload. The axial and radial stiffness of a pair of angular contact ball bearings depends both on the preload and the contact angle.

The following table-values specify the axial stiffness S_a and the radial stiffness S_r for each individual angular contact ball bearing. The same values are true for a pair of angular contact ball bearings of the same type that are set against each other. The relevant factors needed to calculate the preload and stiffness for further sets of high precision angular contact ball bearings are contained in Chapter 2.7 (IBC High precision angular contact ball bearing sets).

The preload stresses the high precision bearings in the same way as outside axial forces do. In dimensioning the rolling bearing, quite often a good balance needs to be struck between preload and stiffness on the one hand and attainable speed and life time on the other.

Due to the lower static load-carrying capacity of the ceramic rolling elements as compared to standard bearings of the same geometry, high precision hybrid rolling bearings have slightly lower preloads. But the stiffness of hybrid bearings is still significantly higher at identical preload, because ceramic rolling elements are harder.

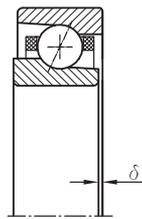

The values for axial and radial stiffness contain parameters that are affected by tolerances that relate to the manufacturing process. The actual stiffness of a rolling bearing may only be determined when it is fitted in its individual mounting situation. For this reason the values in the tables have been rounded up or down; the values are only meant to be used to compare the different kinds of high precision rolling bearings with each other.

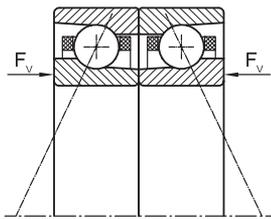

Preloads and stiffness

- F_v preload force of a rolling bearing
- δ preload step of a rolling bearing
- S_a axial stiffness for a pair of bearings in X- or O-arrangement
- S_r radial stiffness for a pair of bearings in X- or O-arrangement
- F_{AK} unloading force that causes loss of preload in the bearings

2.5 Differential measurements for preloads

In order to attain the required stiffness for a bearing's given rotational speed it may become necessary during spindle adjustment to adjust the built-in preload.

This can be achieved with the aid of spacer rings whose difference in length leads to a change in preload class.

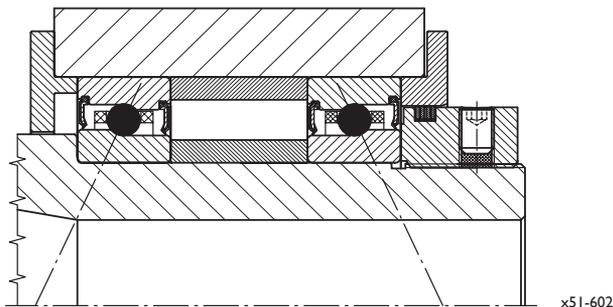

Fig. 2.7: IBC high precision angular contact ball bearings with spacer rings

The differential measurements of the individual preload classes relative to each other are given in the following tables for this purpose. The differential measurement is the distance in μm by which the rings of a single angular contact ball bearing is additionally axially displaced relative to one another in order to achieve the next preload class. For an O-arrangement, for example, shortening the inner spacer ring by the value given in the table makes the preload move up into the next higher class. In an X-arrangement, the same is true for the outer spacer ring. The preload is reduced if the procedure is carried out the other way round.

The measurements of custom-built spacer rings should be carefully documented, and the rings should be kept with the spindle even during repair work. If the spacer rings need to be replaced, the existing differential measurement needs to be determined in order to restore the previous preload with the help of the given differential measurement of the high precision bearings that need to be replaced.

Should the bearing need to carry higher loads, spacer rings that measure the width of the bearing permit subsequent trouble-free insertion of a further rolling bearing.

2.6 IBC High precision universal angular contact ball bearings

All IBC high precision angular contact ball bearings are universally ground. They may therefore be used singly and can be combined to a bearing set arrangement defined by the end-user without any loss of performance. Using universal angular contact ball bearings is a great advantage, especially from the point of view of stocks and the availability of components.

Universal angular contact ball bearings are manufactured as single bearings known as U, and as duplex sets known as DU. Single bearings are marked with a V-marking on the outer ring that allows one to recognise the direction of axial force more easily. The V-marking points in the direction in which the axial force is transmitted through the outer ring. The V-marking also indicates the point of maximum ring thickness. The advantage of universal bearing-sets lies in the fact that their bores and outside diameters are sorted as standard in the IBC manufacturing process.

During manufacture, IBC universal angular contact ball bearings are adjusted and matched in such a way that they can be mounted in any type of arrangement (O- or X-arrangement, or tandem mounting) and with any number of bearings positioned next to each other.

x51-202

Fig. 2.8: Universally ground IBC high precision angular contact ball bearings in O-arrangement, X-arrangement and in tandem mounting

The bearing arrangement is carried out by the customer with the help of the small arrow marker.

In order to facilitate mounting, we also manufacture sets with an additional V-marking that runs on the outer rings, e.g. DB, TBT, QBC, and other combinations.

This is explained in more detail in the following Chapter 2.7 (IBC High precision angular contact ball bearing sets).

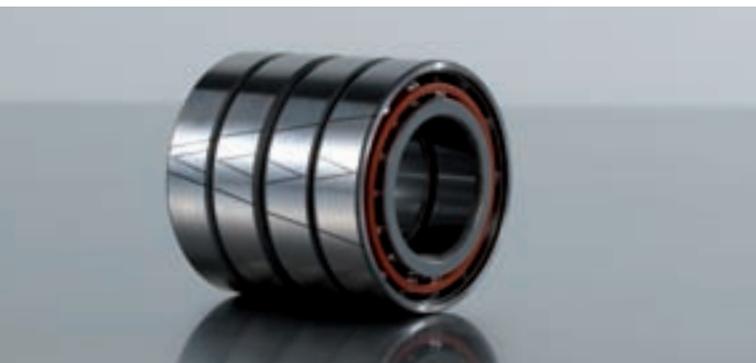

2.7 IBC High precision angular contact ball bearing sets

The minimum mounting for a spindle consists of one high precision angular contact ball bearing on each side. Both bearings are therefore arranged at a suitable distance from each other. In this arrangement, the required preload adjustment is carried out by means of a suitable locknut with a defined tightening torque or with a suitably ground flange cover.

The correct adjustment of the two individual high precision angular contact ball bearings is crucial for the successful operation of this type of bearing arrangement. If the adjustment is not carried out correctly, the life time of the bearing may be reduced through higher friction losses and associated higher operating temperatures.

If the load carrying capacity of a single bearing is insufficient, or should the bearing need to absorb axial forces in both directions, then high precision angular contact ball bearings with universally ground-in preload can be used in sets.

During manufacture, IBC high precision angular contact ball bearing sets are pre-adjusted and matched to each other in such a way as to maintain the predefined preload value of a single bearing within the set and to ensure that the load bearing capacity within the angular contact ball bearing set is spread evenly across the individual bearings.

Arrangements

The O- and X-arrangements of two high precision angular contact ball bearings allow for an axial load to be absorbed in both directions, as shown in fig. 2.8. High axial forces in only one direction are supported by tandem mounting. Forces that are even stronger are absorbed by high precision angular contact ball bearing sets with more than two high precision angular contact ball bearings positioned in a single direction. The angular contact ball bearing set is therefore generally set against a further angular contact ball bearing, or a further set, that absorbs the axial load in the opposite load direction.

Because the effective load centre is wide, the O-arrangement is better suited to absorb tilting moments.

That is why angular contact ball bearing sets with this type of arrangement produce a relatively rigid bearing. In contrast to the O-arrangement, the effective load centre in the X-arrangement is narrow and the X-arrangement is therefore less rigid but slightly more tolerant towards tilting.

With tandem mounting, the contact lines run parallel to each other and at the same angle to the separating line of the angular contact ball bearing.

IBC also offers other high precision angular contact ball bearing sets. Should the design used not permit the setting of angular contact ball bearings in tandem mounting against a further contact ball bearing, or against another set of contact ball bearings, then it is possible to combine tandem mounting with an O- or X-arrangement, for instance. If there are special requirements with regard to stiffness and bearing load, then it is advisable to use tandem mountings with three or four angular contact ball bearings.

Table 2.1: Designation system of IBC high precision angular contact ball bearing sets

Bearing sets and marking

Angular contact ball bearing sets with different combinations are used, depending on the requirements that have to be met. In order to meet these requirements, IBC manufactures matched angular contact ball bearing sets in addition to single bearings. These sets are provided with a V-marking that spans the whole set, in addition to the individual V-marking on the single bearing.

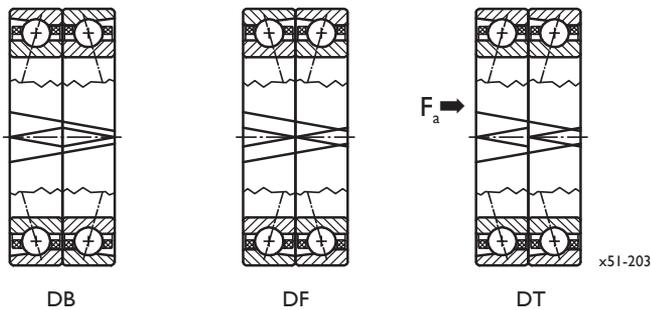

Fig. 2.9: Arrangements with duplex sets

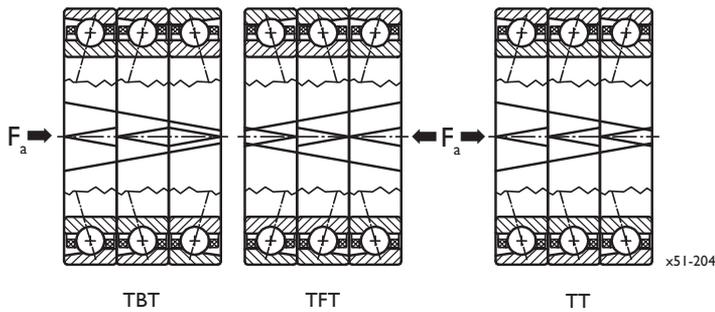

Fig. 2.10: Arrangements with triplex sets

The sequence of the individual bearings is clearly defined by the marking within the set and the marking also indicates the main direction of axial load of the angular contact ball bearing set.

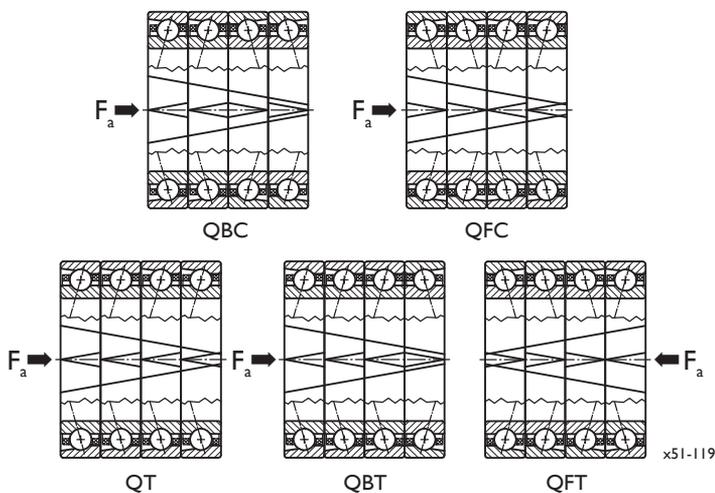

Fig. 2.11: Arrangements with quadruplex sets

The correct mounting direction must be observed so as not to impair the functioning of the angular contact ball bearing set and in order to allow for the adjustment of the built-in preload to be utilised. The marking on the set helps check the exact arrangement of the high precision angular contact ball bearings on the shaft, even after mounting. The marking also helps reduce potential mounting errors.

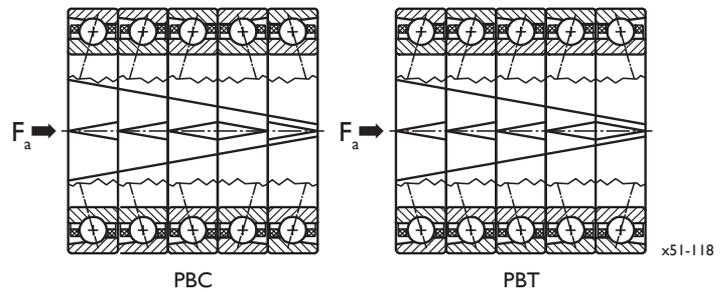

Fig. 2.12: Arrangements with pentaplex sets

The inner ring faces are marked with a small circle 'o' at the point of maximum ring thickness and/or maximum radial runout. When installing high precision angular contact ball bearing sets, care should be taken to ensure that the circles on both the outer and inner rings are aligned. The best possible radial runout is achieved if the outer ring marker is aligned with the point of the largest housing bore and the inner ring marker is aligned with the point of the smallest shaft diameter.

In order to achieve balanced load bearing characteristics for all the angular contact ball bearings within a set, high precision angular contact ball bearings with the same restricted outer and inner ring tolerance are combined. The measurements Δ_{Dmp} and/or Δ_{dmp} of these angular contact ball bearings are specified as average values D_{gm} and/or d_{gm} with regard to their tolerance classes and marked as such on the external packing and foil bag. Chapter 4 (Tolerances) contains detailed information on tolerances and their designation as well as their respective characteristics.

Bearing sets with balanced preload

In addition to arrangements of high precision angular contact ball bearings where each bearing has the same preload, we also supply balanced angular contact ball bearing sets. In this type of arrangement, high precision angular contact ball bearings with single preload are combined with a high precision angular contact ball bearing having double or triple preload value.

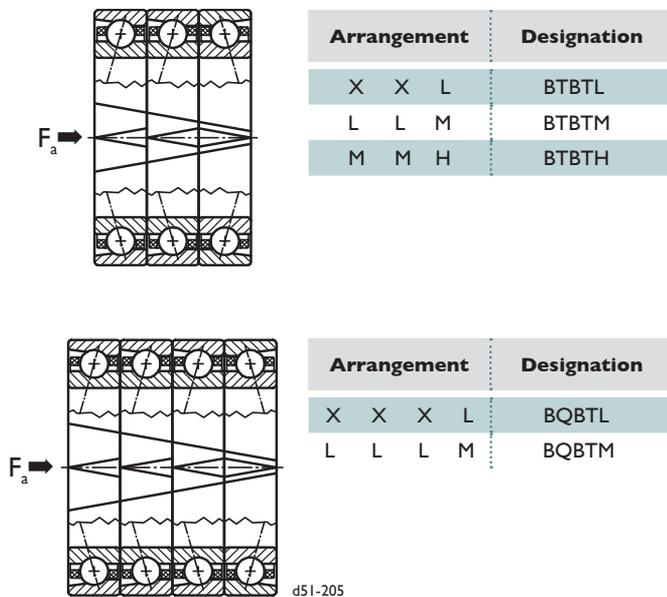

Fig. 2.13: Balanced bearing sets

The use of these arrangements is especially advisable if a high precision angular contact ball bearing is combined with more than one bearing and the preload relief of the single bearing is to be safely avoided.

Misalignment

Misalignment generally should be avoided. Skewing leads to a certain amount of compulsory rotation, which in turn leads to higher running noise and a reduction in bearing life time. The X-arrangement is slightly less susceptible to misalignment than the O-arrangement.

Rotational speed factors for angular contact ball bearing sets

The rotational speeds mentioned in the tables above are based on a high precision single angular contact ball bearing that is lightly preloaded. Because they are subject to self heat generation, preloaded high precision angular contact ball bearings that are combined to form sets do not permit permanent operation with the rotational speeds given in the tables. Various reduction factors apply to these sets, depending on the arrangement of the high precision angular contact ball bearings in the set and on their preload.

Detailed information on rotational speed factors is contained in Chapter 6 (Speed coefficients).

Preload and stiffness of bearing sets

The numerical values for preload and stiffness given in the tables are valid for the individual high precision angular contact ball bearing. A significant change in axial stiffness will occur, however, depending on the way the angular contact ball bearings are arranged within the set and also depending on the direction of the force.

The radial stiffness of a set of angular contact ball bearings, calculated as the sum of the radial stiffness of all the individual bearings, is approximately valid only for those angular contact ball bearing sets in a symmetrical arrangement that also have an absolutely uniform load distribution between the angular contact

ball bearings within the bearing set. Angular contact ball bearing sets in an asymmetrical arrangement are subject to a reduction in stiffness under radial load due to the effect of the slightly differing contact angles.

Table 2.2 below is valid for the different types of arrangements of angular contact ball bearings in bearing sets, and for both directions of axial force. The table specifies the factors for axial and radial stiffness as well as the factor that shows the axial force of angular contact ball bearings within the set that will cause a relief of load, when compared to the preload.

Load in main load direction	axial stiffness factor	radial stiffness factor	un-loading force	Opposite load direction	axial stiffness factor	radial stiffness factor	un-loading force
	K_a	K_r	$X \cdot F_v$		K_a	K_r	$X \cdot F_v$
	1.00	1.00	2.83		1.00	1.00	2.83
	1.63	1.45	5.66		1.30	1.45	2.83

Table 2.2: Stiffness factors and deloading force for angular contact ball bearing sets

2.8 IBC High precision locknuts

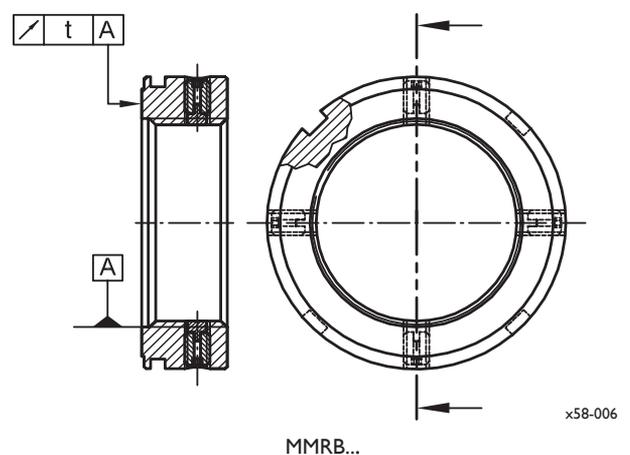

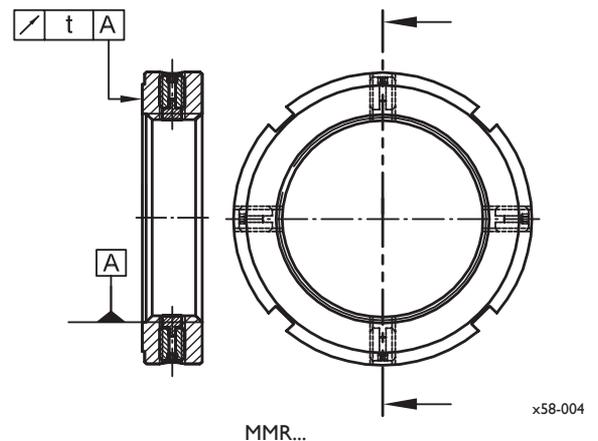

IBC High precision locknuts with fine thread are used with high-precision applications because of their high accuracy. The securing systems integrated into the various locknuts permit simple and accurate mounting and provide for lasting stability.

The securing systems do not change the circular cross-section of the shaft, and no additional changes occur, so the securing systems do not cause grooves to form on the shaft. Because of the superfinishing of the thread and the contact surface, IBC high precision locknuts attain an axial face runout that conforms to ISO standard tolerance class IT3.

The different designs of IBC high precision locknuts are suited to a wide range of applications. The high precision locknuts are manufactured in various widths suitable for different axial loads. The securing devices may be axially or radially accessible, depending on the design. A design fitted with an additional labyrinth seal can also be supplied.

Dimensional series

Precision locknuts from the MMR series are designed for applications with limited installation space, or in order to save weight. In the MBA and MBC series, the locking of a precision locknut which cannot be reached radially is secured axially with accessible clamping screws. This production series requires a greater width due to its specific design. The permissible axial load is the same as for the MMR precision locknut. Starting from a thread diameter of 45 mm, the locknuts of the MBC series are also manufactured with four internal hexagon socket screws, to prevent break-out occurring during fast acceleration. The MMRB execution has a radial securing device, and its cross-section is the same as the MBA and MBC precision locknuts; it therefore permits higher loads and higher tightening torques. Under the designation MMRBS and MBAS, the MMRB and MBA production series are also manufactured with an integrated labyrinth seal.

Overview of the series	
MMR	narrow precision locknut with radial locking
MMRB	wide precision locknut with radial locking
MBA	precision locknut with axial locking via slotted segments and grub screws
MBC	precision locknut with axial locking via slotted segments and screws

Information on the recommended precision locknut for the respective high precision bearings can be found in the last column of the angular contact ball bearing data tables.

Fig. 2.14: IBC high precision locknuts MMR and MMRB

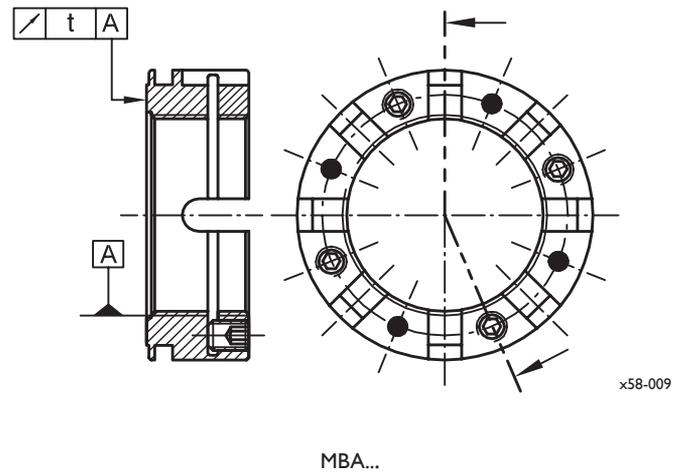

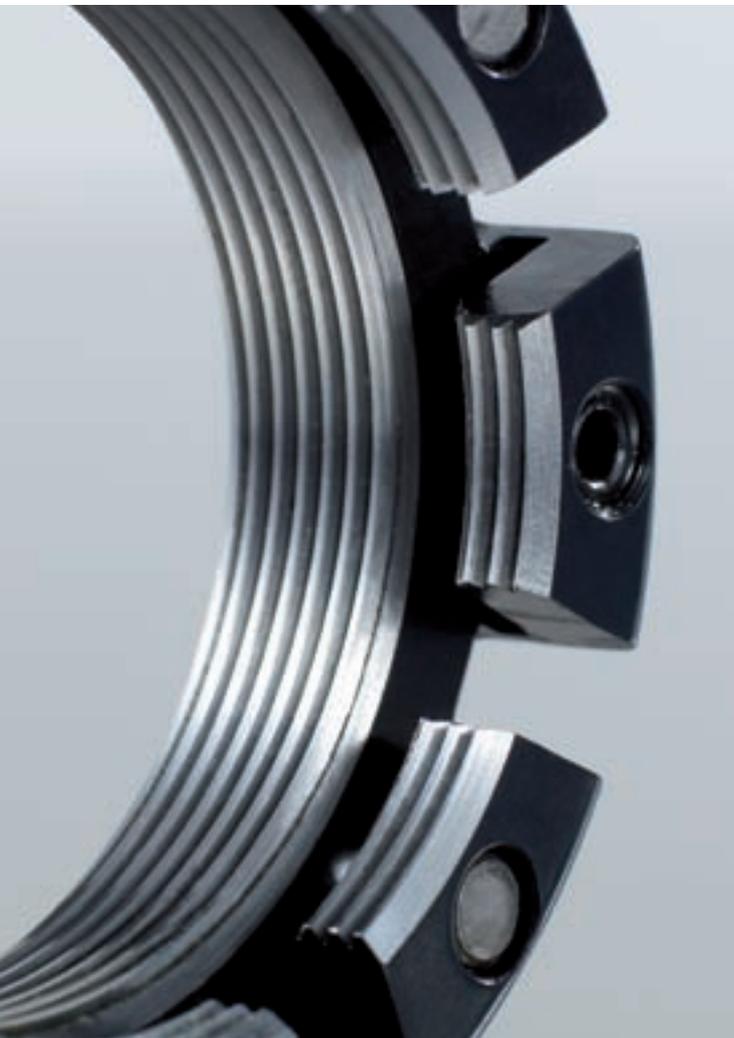

Fig. 2.15: IBC high precision locknut MBA

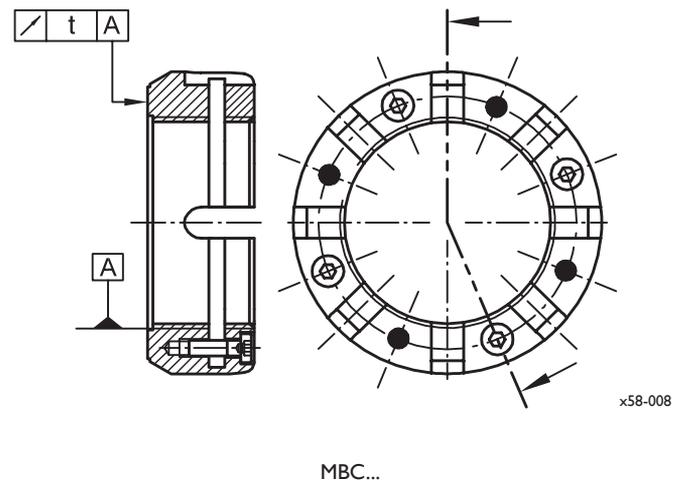

Fig. 2.16: IBC high precision locknut MBC

Chapter 8 (Mounting of High precision rolling bearings) contains more detailed information on the fitting of high precision locknuts as well as on the required tightening torque for each dimensional series of IBC high precision angular contact ball bearings.

If you are using high precision angular contact ball bearings of the 718... dimensional series, the high-precision locknuts may project above the outside diameter of the high precision angular contact ball bearings. In this case you will need to fit a spacer ring.

The publication **Precision Locknuts TI-I-5020** contains more detailed information on the product range and all technical data for the many types of IBC precision locknuts.

3. IBC High Precision Cylindrical Roller Bearings

3. IBC High precision cylindrical roller bearings

The use of high precision rolling bearings in machine tools makes great demands on the running accuracy of these bearings. IBC high precision cylindrical roller bearings combine running accuracy characteristics with great stiffness and load carrying capacity while at the same time providing for a high speed-capacity with a smaller cross section height. This smaller cross section height allows for lower centre distances for multi-spindle arrangements. High precision cylindrical roller bearings make for ideal floating bearings because they are able to compensate for heat-related changes in length that occur in adjacent parts.

IBC high precision cylindrical roller bearings with cages are available in many different variations. They are manufactured as single row bearings in the 19 and 10 dimensional series, and as double row bearings in dimensional series 30 and 49. The bore diameter and outside diameter of both the single and double row cylindrical roller bearings are identical for the particular diameter series.

The high precision cylindrical roller bearings with the HN designation have an enhanced inner geometry that has been adapted to the high precision angular contact ball bearings and their rotational speed capacity. These bearings are the ideal complement to the performance range of the high precision cylindrical roller bearings.

Fig. 3.1: High precision cylindrical roller bearings from the CR HN... design (option Q852)

High precision cylindrical roller bearings with tapered bore are designated by the suffix K and manufactured with a taper angle of 1:12. They are mostly used in machine tool manufacture, because the tapered bore allows for adjustment of the radial clearance and preload by means of axial displacement on the corresponding taper of the shaft.

Designs

The rolling elements of high precision cylindrical roller bearings are guided between two fixed shoulders that are either positioned on the outer ring (NNU) or on the inner ring (N and NN). The other rolling bearing ring of the two does not have any shoulders. Both in the case of the single and the double row precision cylindrical roller bearings, the bearing ring with the fixed shoulders and the roller assembly may be separated from the non shoulder bearing ring, i.e., the bearings are not self-retaining. This greatly contributes towards simpler mounting and dismounting of the rolling bearings.

IBC high precision cylindrical roller bearings are characterised by an ideal combination of load carrying capacity, stiffness and achievable rotational speeds. NNU design rolling bearings achieve great system stiffness in bearing situations that are characterised by very low-profile construction; however, in comparison to the NN design they have a lower load carrying capacity.

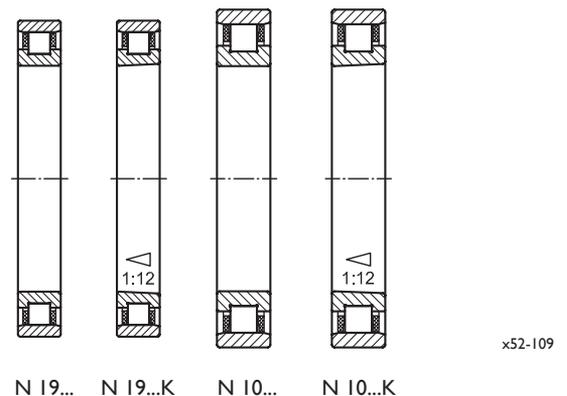

Fig. 3.2: Single row IBC high precision cylindrical roller bearings

The single row high precision cylindrical roller bearings from the dimensional series 19 and 10 are designed as speed-optimised rolling bearings. A further increase in rotational speed may be achieved by cutting the number of rollers in half (option Q852) or by using ceramic rollers (option CR).

Fig. 3.3: High precision cylindrical roller bearings from the N... design with lubrication groove and O-rings (option S)

The cylindrical roller bearings with the suffix S have a circular groove and radial supply holes for direct lubrication. O-rings integrated into the outer rings provide a seal in the housing.

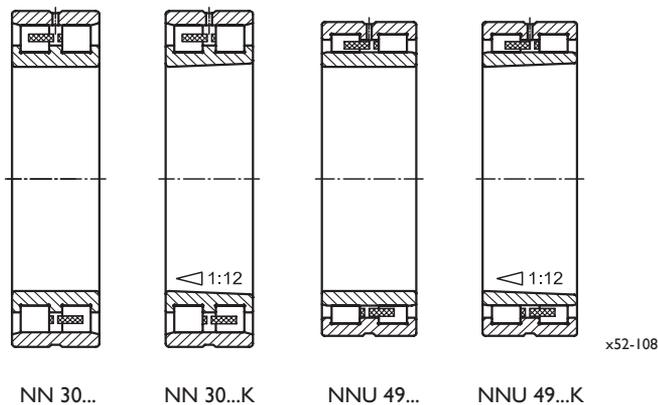

Fig. 3.4: Double row IBC high precision cylindrical roller bearings

All double row IBC high precision cylindrical roller bearings are fitted with a lubrication groove with three holes on the outer ring (designation W33, 120° arrangement) in order to guarantee effective lubrication.

High precision cylindrical roller bearings with outer-ring lubrication reduce the number of elements that are part of the ambient design of the bearing; this results in more installation space, and it also reduces system costs.

Designs that utilise ceramic rolling elements permit higher speeds and have greater system stiffness. Both factors lead to higher-quality machining results. The stress to the rolling bearing itself is also reduced, which in turn leads to lower heat generation within the bearing. This fact has a positive impact on lubrication service life and leads to longer maintenance intervals. A further advantage of hybrid rolling bearings is that they are much less sensitive to high acceleration or deceleration.

Other production series may also be manufactured with ceramic rollers upon request. The hybrid version of these high precision cylindrical roller bearings is suitable for the highest rotational speeds; this comes at the cost of a reduced static load rating, however.

IBC high precision cylindrical roller bearings from the NN, NNU and N designs only absorb radial forces. They permit unconstrained axial displacement inside the rolling bearing in both directions between the shaft and the housing. The maximum permitted axial displacement is specified by the value s in the tables.

Special designs

IBC manufactures special designs of high precision cylindrical roller bearings for specialised applications. Please contact our applications engineers in this case. They will be glad to help you find a solution to your special applications requirements and bearing designs.

Bearing materials

Rolling bearing rings and rolling elements are manufactured from vacuum degassed bearing steel 100Cr6 (1.3505). Rolling elements are also available in the ceramic material silicon nitride Si_3N_4 . A detailed description of materials is included in Chapter 9 (Materials).

Heat treatment

As standard, the bearing rings are stabilised up to a service temperature of 150 °C. For higher temperatures higher-quality heat treatment is available upon request.

Outside the machine tool industry, cylindrical roller bearings with higher heat stabilisation, especially NNU bearings, are used with greater bearing clearance.

Further details like designation, limitations and suitability are contained in Chapter 9 (Materials).

Cages

Various cage options are available depending on the design and the dimension of the high precision rolling bearing. A detailed description of the individual cage materials is included in Chapter 9 (Materials). Please contact our technical service department if your rolling bearing needs cages that have to meet special requirements.

Bearings with ATCoat coating

Besides the executions already mentioned, IBC also manufactures high precision bearings with an ATCoat thin dense chromium coating.

You will find a detailed description of the ATCoat coating in Chapter 10 (IBC High precision rolling bearings with ATCoat coating) and particularly in the publication **ATC Technology Coatings**.

Tolerances

IBC high precision cylindrical roller bearings are manufactured to conform to tolerance class SP as standard, but higher accuracies are possible. You will find the exact values in the tables in Chapter 4 (Tolerances).

The radial clearance of high precision cylindrical roller bearings with tapered bore is greater than that of cylindrical roller bearings with cylindrical bore. On request, we also manufacture tapered bore bearings with the smaller clearance of cylindrical roller bearings with cylindrical bore. This is especially beneficial in the adjustment of the bearings. Detailed information on this can be found in Chapter 8 (Mounting of High precision rolling bearings).

Misalignment

It should be noted that in the case of high precision cylindrical roller bearings misalignment leads to a certain amount of compulsory rotation. This in turn leads to higher running noise and may also result in a reduced life time.

Please contact our technical application teams in cases where misalignment may occur. Misalignment of the inner ring in reference to the outer ring that is permissible and does not reduce the life time, depends on the load ratio c/p (dynamic load rating to dynamically equivalent bearing load) and should be checked in each case.

4. Tolerances

4. Tolerances

Tolerance classes

The desire for rolling bearings with ever greater precision has led to the introduction of a range of tolerance classes with an increasing number of subdivisions.

Various tolerance classes have been established and are currently in use, each with its own designations.

Description of tolerance classes

Existing tolerance classes have been described by various organisations. The designation of the classes differs, however, according to the manufacturer.

IBC Designation Descriptive organisation	P5	P4	P4A	P2H	P2A
DIN (German Standards Institute)	P5	P4	P4S		P2
AFBMA STD 20 (Anti-Friction Bearing Manufacturers Association)	ABEC5	ABEC7			ABEC9
ISO 492 (International Standards Organisation)	Class 5	Class 4			Class 2
BS 292 (British Standards Institution)	EP5	EP7			EP9

Comparison between manufacturers					
FAG	P5	P4	P4S	(P4S)	
NSK	P5	P4	P3	(P3)	P2
SKF	P5	P4	P4A	(P4A)	PA9A
SNFA		7	7/9		9

Table 4.1: Tolerance classes and descriptive organisation

Abbreviation according to ISO	Tolerance characteristics				
	Inner ring characteristic	P4	P4A	P2H	P2A
Δ_{dmp}	Deviation of the mean bore diameter from the nominal	P4	P4	P4	P2
K_{ia}	Radial runout of assembled bearing inner ring	P4	P2	P2	P2
S_d	Side face runout with reference to bore of the inner ring	P4	P2	P2	P2
S_{ia}	Side face runout of the assembled bearing inner ring	P4	P2	P2	P2
V_{Bs} / V_{Cs}	Ring width variation	P4	P4	P2	P2
$\Delta_{Bs} / \Delta_{Cs}$	Deviation of inner ring width	P4	P4	P4	P2

Abbreviation according to ISO	Outer ring characteristic				
	P4	P4A	P2H	P2A	
Δ_{Dmp}	Deviation of the mean outside diameter from the nominal	P4	P4	P4	P2
K_{ea}	Radial runout of assembled bearing outer ring	P4	P2	P2	P2
S_D	Variation in inclination of outside cylindrical surface to outer ring side face	P4	P2	P2	P2
S_{ea}	Side face runout with reference to raceway of assembled bearing outer ring	P4	P2	P2	P2

Table 4.2: Allocation to tolerance classes according to DIN 620

4.1 Dimensions and measuring principles

IBC High precision rolling bearings

The basic dimensions of a high precision rolling bearing comprise its bore d , its outside diameter D and its width B . The basic dimensions also include the tolerances for the bore Δ_{dmp} as well as for the outside diameter Δ_{Dmp} . The tolerance for the width Δ_{Bs} depends on the bore of the inner ring and is applicable to both bearing rings.

The accuracy for the running of a rolling bearing is also subject to defined tolerances. Apart from the desired rotation around the

central axis of the high precision rolling bearing, unwanted displacements and tilting movements occur in both axial and radial directions. There are maximum values and/or limit values for these effects too. In most mounting situations, the maximum radial runout of the inner ring K_{ia} is especially important. IBC high precision angular contact ball bearings are manufactured as standard to conform to tolerance classes P4A, P2H and P2A. The high precision cylindrical roller bearings are manufactured to conform to tolerance class SP as standard.

Table 4.4: Dimensional and running tolerances for the outer ring, specified in μm .

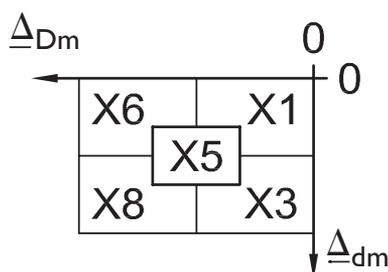

4.3 Sorting and chamfer dimensions

IBC High precision rolling bearings

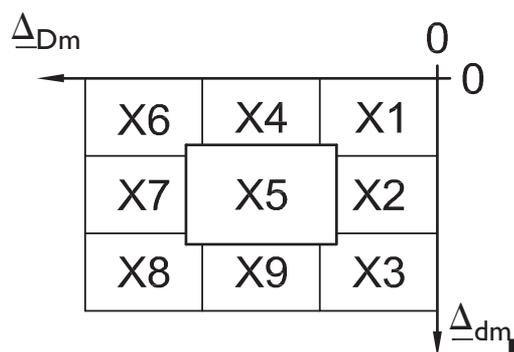

Sorting

The dimensional tolerances of the bearing, along with the dimensional tolerances of the housing, determine the exact and reproducible locating-bearing or floating-bearing fit of a high precision rolling bearing. In order to simplify the allocation of high precision rolling bearings and bearing sets to shafts and housings, the diameter deviations of IBC high precision rolling bearings are

sorted by bore diameters and outside diameters and are specified with a group mean value. Classifying the permissible overall tolerance for the outside diameter Δ_{Dmp} and the bore Δ_{dmp} in 2 or 3 sorting groups respectively is done on the basis of diameter and quality (P4A, P2H, P2A). Up to an overall tolerance of $5 \mu\text{m}$ there are 2 groups; above that value there are 3 groups. This results in 5 and 9 sorting combinations respectively.

Overall tolerance $\Delta_{dm} \leq 5 \mu\text{m}$

Overall tolerance $\Delta_{dm} > 5 \mu\text{m}$

d40-311

Fig. 4.4: Sorting classes

Chamfer dimensions

The chamfer dimensions are standardised according to the table on the right for all rolling bearings. The chamfers of the adjacent parts, e.g. housing and/or shaft, have to be manufactured accordingly.

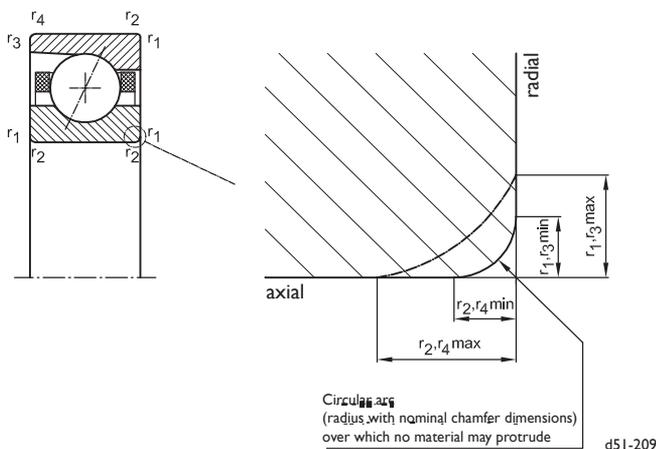

Fig. 4.5: Dimensional drawing of chamfer dimensions according to DIN 620, Part 6

Nominal chamfer dimensions r_{min}, r_{12}, r_{34}	Bore diameter		Tolerance of chamfer dimensions

4.5 Radial clearance

IBC High precision cylindrical roller bearings

As standard, IBC manufactures high precision cylindrical roller bearings to conform to the tolerance class SP with radial clearance C1. The bearing clearance is not explicitly specified. Apart from the class mentioned, further bearing clearance classes are available, e.g. SPC2X or C3.

The bearing rings of high precision cylindrical roller bearings of the same type are not interchangeable.

The values for the bearing clearance of high precision cylindrical roller bearings are different for bearings with cylindrical bore from those with tapered bore, even if they belong to the same tolerance class. When fitting a high precision cylindrical roller bearing on to a tapered shaft it is possible to adjust the bearing clearance specifically via the displacement. This option, and the simple design, make high precision cylindrical roller bearings ideally suited for use in the machine tool industry. Further information on this issue is contained in Chapter 8 (Mounting of High precision rolling bearings).

Design of adjacent parts

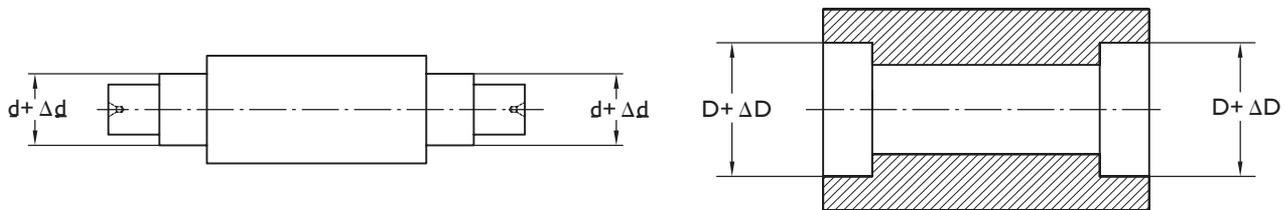

The positional accuracy and form accuracy of the adjacent parts must be adjusted to the accuracy requirements of the high precision rolling bearings. Rolling bearings adapt to form deviations in the shaft and the housing because the bearings have comparatively slender ratios of cross section. The fit selected depends on the rotational conditions of the bearing rings under consideration.

Table 4.13: Interference and/or clearance measurements that should be aimed for with adjacent parts with regard to IBC high precision angular contact ball bearings. For angular contact ball bearings of P2H accuracy, the tolerances for shaft and housing should be according to P2A, if possible. Specifications in μm .

5. Life Time Calculation

5. Life time calculation

Even under suitable operating conditions, and even if the high precision rolling bearings have been mounted properly, a bearing may still fail. The service life of high precision rolling bearings is limited by various factors.

The length of time during which a high precision rolling bearing works satisfactorily is called its "life time". Material fatigue, vibrations, contamination or lubrication-failure may occur during this time span. In the following observations we will be ignoring the causes that can lead to the failure of a high precision rolling bearing without noticeable prior indication; these causes include faulty design, inadequate maintenance, faulty mounting, and wrong bearing dimensioning.

Fatigue

Fatigue of the material that high precision rolling bearings are made of is caused by the rising stress to the material that occurs when high precision rolling bearings rotate under load. Towards the end of the life of the bearing, "pittings" appear on the running surfaces or the rolling elements; an initial occurrence may be followed by progressive pitting of the material.

Various factors are responsible for material fatigue; they can really only be covered with reference to statistics. The definition of a theoretical reference value for "fatigue life time" therefore refers to a very large quantity of rolling bearings running under the same conditions. The fatigue life time is reached as soon as 10% of all bearings have failed. The fatigue life time may be specified with reference to the number of revolutions or to the runtime in hours.

In addition to fatigue life time, lubrication life time is another decisive factor in operating a high precision rolling bearing. Particular rules apply for the calculation of this factor. In the case of high precision rolling bearings that are permanently monitored, other parameters may also be crucial in determining their life time, including temperature, bearing noise and vibrations.

Basic rating life

In terms of pure definition, 10% of a great number of high precision rolling bearings of the same type, running under the same conditions, may fail within a basic rating life of L_{10} . If a constant rotational speed is used, the basic rating life may also be specified in terms of a time $L_{10,h}$.

$$L_{10,h} = \left(\frac{C}{P} \right)^p \cdot \frac{10^6}{60 \cdot n} \quad [\text{h}] \quad [5.1]$$

$L_{10,h}$	basic rating life	[h]
n	operating speed	[min ⁻¹]
C	dynamic load rating	[N]
P	equivalent dynamic bearing load	[N]
p	life time exponent	
	for ball bearing $p = 3$	
	for roller bearing $p = 10/3$	

Dynamic load rating

The dynamic load rating is the constant load of a high precision rolling bearing with a rotating inner ring for which 1 million revolutions will be achieved with a probability of 90%. It is considered as a central radial load that is constant with regard to magnitude and direction. It is based on numerous experiments and is a performance figure that may be calculated with the aid of empirical rules.

Static load rating

The static load carrying capacity of a high precision rolling bearing is defined by the static load rating C_0 . This is the load that a stationary high precision rolling bearing can bear with a maximum permanent plastic deformation of 1/10,000 of the rolling element diameter.

Equivalent dynamic bearing load

Combined loads, comprising both axial and radial components, can often act on high precision rolling bearings. In order to relate the forces that actually act on a high precision rolling bearing to the dynamic load rating, the equivalent dynamic bearing load P is calculated from the effective force components. This load is hypothetical and corresponds to the dynamic load rating with regard to the point of application of the load and its effective direction.

$$P = X \cdot F_r + Y \cdot F_a \quad [N] \quad [5.2]$$

P	equivalent dynamic bearing load	[N]
F_r	radial force	[N]
F_a	axial force	[N]
X	radial load factor, see table 5.1	
Y	axial load factor, see table 5.1	

Once you have calculated the equivalent dynamic bearing load it may be mathematically related to the dynamic load rating in order to determine the life time.

Equivalent static bearing load

The necessary static load rating C_0 is calculated from the equivalent static bearing load P_0 , which is additionally weighted by the static load safety factor s_0 .

$$C_0 = P_0 \cdot s_0 \quad [N] \quad [5.3]$$

C_0	static load rating	[N]
P_0	equivalent static bearing load	[N]
s_0	static load safety factor	

Achieving adequate static load safety depends on the operation of the rolling bearings and on their required running smoothness. High precision angular contact ball bearings require a minimum static safety factor of 1; high precision roller bearings require a minimum static safety factor of 1.5.

If high demands are placed on the running smoothness of the rolling bearing, the above mentioned values for static load safety must be at least doubled. If the rolling bearing is subject to shock impact loads, an additional increase of the static load safety by factor 1.5 is required.

Static load carrying capacity of dynamically designed bearings

If the static load is known, the equivalent static bearing load should be calculated for the type of rolling bearing that was chosen on the basis of the computation of the dynamic load carrying capacity; the equivalent static bearing load should then be checked against the static load safety given above.

Comparing the effective static bearing load with the static load rating also means that the equivalent static bearing load P_0 has to be calculated. Calculation is done in analogy to the calculation of the equivalent dynamic bearing load.

$$P_0 = X_0 \cdot F_r + Y_0 \cdot F_a \quad [N] \quad [5.4]$$

P_0	equivalent static bearing load	[N]
F_r	radial force	[N]
F_a	axial force	[N]
X_0	radial load factor, see table 5.1	
Y_0	axial load factor, see table 5.1	

Determining the axial and radial load factors

To begin with, the axial and radial load factors from table 5.1 are determined for angular contact ball bearings that permit a combined load. The first step for angular contact ball bearings with a contact angle of 15° is to calculate the ratio $F_a / i \cdot C_0$.

In so doing, i stands for the number of high precision rolling bearings in a set. The bearing-related factor e for single bearings or bearing sets with the same alignment is given in table 5.1a; for high precision rolling bearings that are set against each other, the factor e is given in table 5.1b next to the value that comes as close as possible to the outcome of the calculation $F_a / i \cdot C_0$. The factor e may also be interpolated in the relevant manner. In the next step, the ratio of the force components F_a / F_r that impact from the outside is calculated and is compared to the value of the bearing-related factor e that is contained in the respective table.

If the ratio is smaller than e , then the axial component is omitted and only the radial load factor $X = 1$ is retained. If the ratio is greater than e , then the factors X and Y are read off from the same line in the table as their respective factor e . In the case of angular contact ball bearings with a contact angle of 25°, e always has the value of 0.68, and the ratio $F_a / i \cdot C_0$ is not calculated. The static radial load factor X_0 and the static axial load factor Y_0 may be taken straight from tables 5.1a and 5.1b for the different kinds of contact angles and bearing arrangements. There is no need to calculate these factors.

0.446	0.56		1.12		1.63			
25°		0.68	1	0.92	0.67	1.41	1	0.76

Table 5.1b: Factors for calculating the equivalent bearing load for bearing arrangements with a load that impacts symmetrically

Two angular contact ball bearings that are arranged at a distance from one another in an X- or O-arrangement are considered to be a system if there is a symmetrical load application; the system factors for the calculation of the equivalent bearing load are contained in table 5.1b. In all other cases it will be necessary to calculate the individual bearing forces, and the factors will be taken from table 5.1a.

After applying the formulas 5.2 and 5.3, the equivalent dynamic bearing load P and the equivalent static bearing load P_0 will be known.

If the equivalent static bearing load does not exceed the static load rating multiplied by the static load safety s_0 , then the single bearing possesses an adequate static dimension. The equivalent dynamic bearing load for a single bearing is worked out using the life time calculation according to equation 5.1.

The dynamic load rating that is necessary for this calculation is contained in the tables in Chapter 2 (IBC High precision angular contact ball bearings) and Chapter 3 (IBC High precision cylindrical roller bearings) for high precision rolling bearings.

Bearing combinations

Should multiple single-row precision angular contact ball bearings of the same kind be fitted next to each other in the same arrangement, the static overall load rating of this combination is calculated from the individual static load ratings (see below):

$$C_{0,\text{Satz}} = i \cdot C_{0,\text{Einzellager}} \quad [\text{N}] \quad [5.5]$$

$C_{0,\text{Satz}}$	static load rating of bearing set	[N]
i	number of bearings	
$C_{0,\text{Einzellager}}$	static load rating of single bearing	[N]

The dynamic load rating of a set is calculated as follows:

$$C_{\text{Satz}} = i^{0.7} \cdot C_{\text{Einzellager}} \quad [\text{N}] \quad [5.6]$$

C_{Satz}	dynamic load rating of bearing set	[N]
i	number of bearings	
$C_{\text{Einzellager}}$	dynamic load rating of single bearing	[N]

The general reduction in the dynamic load rating of a set by the value $i^{0.7}$ according to DIN ISO 281 is based on the assumption that, within a set, bearings with standard tolerances have bore and outside diameters that differ from each other and therefore carry unequal portions of the load.

Sorted and marked high precision angular contact ball bearings with narrower tolerances carry loads in a much more equal way and therefore result in better operational safety.

The life time of a set of high precision rolling bearings can be calculated if the effective forces that act on each single bearing are known, as the failure of a single high precision rolling bearing within the system leads to the failure of the entire system.

As each single high precision rolling bearing has a 90% probability of reaching its life time, the failure probability of the overall system is the product of the failure probabilities of the single high precision rolling bearings.

In effect, this means that the life time of the overall system is shorter than the shortest life time of any high precision rolling bearing that is part of the system. Taking into account the life times of the single high precision rolling bearings, a system life time $L_{10h,\text{ges}}$ may be calculated using equation 5.7.

$$L_{10h,\text{ges}} = \frac{1}{\left(\frac{1}{L_{10h,1}^{1.1}} + \frac{1}{L_{10h,2}^{1.1}} + \dots + \frac{1}{L_{10h,n}^{1.1}} \right)^{\frac{1}{1.1}}} \quad [\text{h}] \quad [5.7]$$

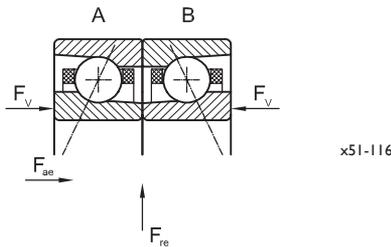

A note on bearing sets with inner preload

The method described above is not valid for preloaded high precision rolling bearings, which are often set against each other in bearing sets, because the preload of these bearings stresses the rolling bearings in addition to the external forces. In order to calculate the life time of a preloaded set of high precision rolling bearings one needs to look at the forces acting on each individual bearing. A method for calculating the life time that takes into account preloading is described on the following pages.

5.1 Detailed calculation of bearing forces

In order to determine the radial and axial load components F_r and F_a of each bearing in an arrangement of preloaded angular contact ball bearings, the external radial loads F_{re} , the external axial loads F_{ae} and the axial preload F_v as well as their load allocation, have to be taken into account. The load allocation may be calculated from the spring compression of the rolling elements that conforms to a power law with the exponent $2/3$; the assumption is that the radial force is equally divided between the single rolling bearings.

A bearing set with two high precision angular contact ball bearings

Due to the wedge effect produced by contact angle α , an external radial load F_{re} changes the whole preload F_v in the following way:

$$F_{v,ges} = \frac{F_{re} \cdot 1.2 \cdot \tan \alpha + F_v}{2} \quad [N] \quad [5.8]$$

if $F_{v,ges} < F_v$, then apply as correction $F_{v,ges} = F_v$

The axial loads of the individual bearings A and B can now be calculated with the adjusted preload $F_{v,ges}$:

$$F_{a,A} = \frac{2}{3} \cdot F_{ae} + F_{v,ges} \quad [N] \quad [5.9]$$

$$F_{a,B} = F_{v,ges} - \frac{1}{3} \cdot F_{ae} \quad [N] \quad [5.10]$$

If the result is $F_{a,A}$ or $F_{a,B} < 0$ the respective high precision rolling bearing is in an unloaded state. The axial load then equals zero, and the axial load of the other bearing corresponds to the external axial load F_{ae} .

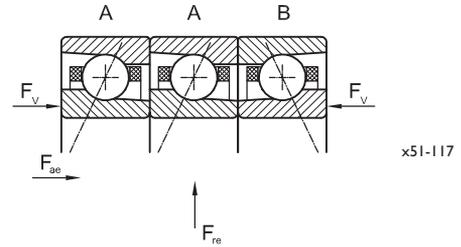

The external radial load F_{re} is now distributed for the single bearings in accordance with the power law of the spring compression mentioned above, taking into account the allocation of the axial loads.

$$F_{r,A} = \frac{F_{a,A}^{2/3}}{F_{a,A}^{2/3} + F_{a,B}^{2/3}} \cdot F_{re} \quad [N] \quad [5.11]$$

$$F_{r,B} = \frac{F_{a,B}^{2/3}}{F_{a,A}^{2/3} + F_{a,B}^{2/3}} \cdot F_{re} \quad [N] \quad [5.12]$$

From the axial loads $F_{a,A}$ and $F_{a,B}$ and the radial loads $F_{r,A}$ and $F_{r,B}$ which have been obtained by the above method, the equivalent dynamic bearing load for each high precision rolling bearing is now determined in accordance with equation 5.2. Factors X and Y are taken from table 5.1a. The application of equation 5.1 gives an individual life time for each high precision rolling bearing, and these life time values are then combined in accordance with equation 5.7 to obtain the system life time.

A bearing set with three high precision angular contact ball bearings

Taking into account an external radial load, the following is true for the preload of the individual high precision rolling bearings:

$$F_{v,A} = \frac{F_{re} \cdot 1.2 \cdot \tan \alpha + F_v}{4} \quad [N] \quad [5.13]$$

$$F_{v,B} = \frac{F_{re} \cdot 1.2 \cdot \tan \alpha + F_v}{2} \quad [N] \quad [5.14]$$

if $F_{v,A} < F_v/2$, then apply as correction $F_{v,A} = F_v/2$
and $F_{v,B} < F_v$ then apply as correction $F_{v,B} = F_v$

Therefore the axial loads of the individual high precision rolling bearings are obtained from the following calculation:

$$F_{a,A} = 0.4 \cdot F_{ae} + F_{v,A} \quad [N] \quad [5.15]$$

$$F_{a,B} = F_{v,B} - 0.2 \cdot F_{ae} \quad [N] \quad [5.16]$$

If $F_{a,B} < 0$ then there is no more preload. The axial load of high precision rolling bearing B is zero, and the two high precision rolling bearings A each carry half the external axial load. In the opposite case, both high precision rolling bearings A are unloaded and are no longer subject to axial load. In this case, high precision rolling bearing B carries the full external axial load F_{ae} .

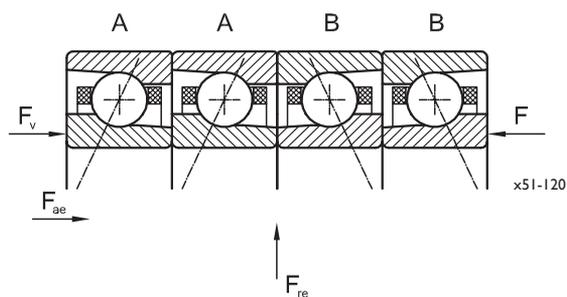

The radial load rate for each high precision rolling bearing with regard to the external radial force is as follows:

$$F_{r,A} = \frac{F_{a,A}^{2/3}}{2 \cdot F_{a,A}^{2/3} + F_{a,B}^{2/3}} \cdot F_{re} \quad [\text{N}] \quad [5.17]$$

$$F_{r,B} = \frac{F_{a,B}^{2/3}}{2 \cdot F_{a,A}^{2/3} + F_{a,B}^{2/3}} \cdot F_{re} \quad [\text{N}] \quad [5.18]$$

As in the case mentioned above, the equivalent dynamic bearing load is obtained by further calculation using equation 5.2 in conjunction with table 5.1a that contains the axial and radial load factors. From there, equation 5.1 leads to the life time of the individual bearings, and equation 5.7 then produces the life time of the overall system.

A bearing set with four high precision angular contact ball bearings

Because of the contact angle of angular contact ball bearings, the radial load influences the preload of the individual high precision rolling bearings as follows:

$$F_{v,ges} = \frac{F_{re} \cdot 1.2 \cdot \tan \alpha + F_v}{4} \quad [\text{N}] \quad [5.19]$$

if $F_{v,ges} < F_v / 2$, then apply as correction $F_{v,ges} = F_v / 2$

The axial loads of the individual high precision rolling bearings are thus obtained by doing the following calculation:

$$F_{a,A} = \frac{1}{3} \cdot F_{ae} + F_{v,ges} \quad [\text{N}] \quad [5.20]$$

$$F_{a,B} = F_{v,ges} - \frac{1}{6} \cdot F_{ae} \quad [\text{N}] \quad [5.21]$$

If $F_{a,B} < 0$ then there is no more preload. The axial load of high precision rolling bearings B is zero, and the two high precision rolling bearings A each carry half the external axial load. In the opposite case, both high precision rolling bearings A are unloaded and are no longer subject to axial load. In this case the high precision rolling bearings B each carry half the axial load F_{ae} .

The radial load rate for each high precision rolling bearing with regard to the external radial force is as follows:

$$F_{r,A} = \frac{F_{a,A}^{2/3}}{F_{a,A}^{2/3} + F_{a,B}^{2/3}} \cdot \frac{F_{re}}{2} \quad [\text{N}] \quad [5.22]$$

$$F_{r,B} = \frac{F_{a,B}^{2/3}}{F_{a,A}^{2/3} + F_{a,B}^{2/3}} \cdot \frac{F_{re}}{2} \quad [\text{N}] \quad [5.23]$$

Further calculation is carried out by applying equation 5.2 in conjunction with table 5.1a, as well as equation 5.1 and 5.7; this gives the life time of the overall bearing system.

Further combinations of angular contact ball bearings

Departing from the above calculation, and taking into account the uneven distribution of the load in accordance with equation 5.24, if axial load predominates, the calculation of the life time may be carried out with defined load parameters according to table 5.2.

In order to determine the resulting axial bearing load, the bearing preload F_v needs to be taken into account along with the external load F_{ae} . In bearing arrangements with an unequal number of bearings per load direction, this results in variable axial stiffness, axial load ratings and life times, depending on the number of bearings for each direction. The proportion of the preload and the external load that needs to be taken into account for each bearing is contained in table 5.2.

For bearing sets made up of universal bearings with more than two bearings and a rigid preload F_v that cannot to be ignored, the life time for each single bearing should be calculated as follows.

The radial load is distributed between all the high precision rolling bearings in a set:

$$F_{r, \text{Einzellager}} = \frac{F_r}{i_{ges}^{0.7}} \quad [\text{N}] \quad [5.24]$$

		Number of bearings in a set					
i		1	2	3	4	5	6
$i^{0.7}$		1	1.62	2.12	2.64	3.09	3.51

The axial load $F_{a, \text{Einzellager}}$ results from the formulas in accordance with table 5.2. The high precision rolling bearings in load direction experience the greatest stress. The high precision rolling bearings in counter-load direction only carry part of the preload or are completely unloaded.

The equivalent bearing loads P are then determined in each case with the help of the resulting bearing loads $F_{r, \text{Einzellager}}$ and $F_{a, \text{Einzellager}}$ according to formula 5.2.

If a variable spring preload is used instead of a rigid preload, the following is true for the high precision rolling bearing (or bearing set) that experiences more stress:

$$F_a = F_{Feder} + F_{ae} \quad [N] \quad [5.25]$$

$$F_{a, \text{Einzellager}} = \frac{1}{i^{0.7}} \cdot (F_{Feder} + F_{ae}) \quad [N] \quad [5.26]$$

Load spectrums

For a load spectrum made up of forces that change over time, and possibly including variable speeds, a mean equivalent bearing load is determined in accordance with equation 5.27.

The mean rotational speed itself is also made up of portions of time for the respective speeds that are expressed as a percentage.

$$P_m = \sqrt[3]{\frac{P_1^3 \cdot t_1 \cdot n_1 + \dots + P_n^3 \cdot t_n \cdot n_n}{n_m \cdot 100}} \quad [N] \quad [5.27]$$

$$n_m = \frac{t_1 \cdot n_1 + \dots + t_n \cdot n_n}{100} \quad [\text{min}^{-1}]$$

P_m mean bearing load [N]
 $P_1 \dots P_n$ equivalent load per load case [N]
 $t_1 \dots t_n$ time portion of bearing load [%]
 $n_1 \dots n_n$ service speeds [min⁻¹]
 n_m mean operating speed [min⁻¹]

Determining the bearing size

After preselecting a possible arrangement of high precision angular contact ball bearings, and after applying the equations mentioned above to the given external bearing loads and to the assumed preload of the bearings, all individual equivalent dynamic bearing loads P are known.

After adjusting equation 5.1 as follows

$$C = P \cdot \sqrt[3]{\frac{L_{10,h} \cdot 60 \cdot n}{10^6}} \quad [N] \quad [5.28]$$

C dynamic load rating [N]
 P equivalent dynamic load [N]
 p life time exponent
 L_{10,h} basic rating life [h]
 n operating speed [min⁻¹]

the required dynamic load rating may be determined by assuming a life time for a given speed; the dynamic load rating may then be used for purposes of comparison with the table.

Load direction	Arrangement bearing position		Load direction	Unloading from $F_{ae} > X \cdot F_v$	Load distribution with regard to single bearing (F_a , Einzellager) taking into account preload F_v and external load F_{ae}			
	A	B			up to unloading through external load $F_{ae} < X \cdot F_v$		after unloading at $F_{ae} > X \cdot F_v$	
	A	B		X	A	B	A	B

$F_{ae} \rightarrow$	<<	>>		5.66	$0.84 F_v + 0.40 F_{ae}$	$0.84 F_v - 0.22 F_{ae}$	$0.617 F_{ae}$	0
$F_{ae} \rightarrow$	<<<	>>		8.49	$1.12 F_v + 0.33 F_{ae}$	$1.49 F_v - 0.18 F_{ae}$	$0.463 F_{ae}$	0
	<<<	>>	$\leftarrow F_{ae}$	5.66	$1.12 F_v - 0.20 F_{ae}$	$1.49 F_v + 0.35 F_{ae}$	0	$0.617 F_{ae}$
$F_{ae} \rightarrow$	<<<<	>>		11.3	$1.03 F_v + 0.29 F_{ae}$	$1.68 F_v - 0.15 F_{ae}$	$0.379 F_{ae}$	0
	<<<<	>>	$\leftarrow F_{ae}$	8.49	$1.03 F_v - 0.18 F_{ae}$	$1.68 F_v + 0.33 F_{ae}$	0	$0.617 F_{ae}$

5.2 Expanded modified life time calculation

Over the years, the method of calculating the life time of a high precision rolling bearing has become more sophisticated by the inclusion of new criteria. The calculating method that was applied used to consist solely of a function of load rating C, of the equivalent dynamic bearing load P and of the mean operating speed n_m . But various other life time coefficients have been added over time.

Expanded modified life time calculation

The so-called modified life time L_{na} with its factors a_1 , a_2 and a_3 that was commonly used in the past has been superseded by the expanded modified life time calculation $L_{10, nm}$ according to DIN ISO 281 as of 1993.

$L_{10, nm} = a_1 \cdot a_{DIN} \cdot L_{10}$	[h]	[5.29]
$L_{10, nm}$	expanded modified life time	[h]
a_1	life time expectation	
a_{DIN}	life cycle coefficient as in equation 5.37 to 5.42	
L_{10}	life time as in equation 5.1	[h]

life time expectation a_1		
life time expectation %	L_{na}	a_1
90	L_{10a}	1.00
95	L_{5a}	0.62
96	L_{4a}	0.53
97	L_{3a}	0.44
98	L_{2a}	0.33
99	L_{1a}	0.21

Table 5.3: Coefficients a_1

The probability factor a_1 remains. This factor permits the conversion of the life time expectation of 90%, or the failure rate of 10%, to other, higher life time expectations. The a_{DIN} factor that has now been introduced covers various parameters that are listed below.

In addition to load, the following parameters are taken into account, which in turn are based on multiple factors:

Parameter	Influenced by
Lubrication	bearing size, speed, viscosity and type of lubricant, additives
Material	surface, purity, hardness, temperature resistance, fatigue limit
Bearing design	friction conditions, internal load distribution
Tension	manufacturing, heat treatment, press fit
Bearing ambience	moisture, contamination of lubricant
Mounting	displacement, damage

Table 5.4: Parameters

The expanded modified life time calculation is based on the basic rating life L_{10} in accordance with equation 5.10, weighted by the life time expectation factor a_1 in accordance with table 5.3 and the life cycle coefficient a_{DIN} .

Determining the life cycle coefficient

The life cycle coefficient a_{DIN} is read off from diagrams 5.3 and 5.4, after the parameters $e_c \cdot P_u / P$ and κ have been determined, or it is calculated in accordance with equations 5.37 to 5.42.

$$a_{DIN} = f \left(\frac{e_c \cdot P_u}{P}, \kappa \right) \quad [5.30]$$

a_{DIN}	life cycle coefficient	
e_c	contamination coefficient (table 5.5)	
P_u	fatigue limit load	[N]
P	equivalent dynamic bearing load	[N]
κ	viscosity ratio	

Fatigue limit load

This takes into account the fatigue limit of the ring material. Without going into detail here, the fatigue limit load is roughly defined with the aid of the following formula for rolling bearings up to a mean bearing diameter d_m of 150 mm:

$P_u \cong C_0 / 27$	ball bearing	[N]	[5.31]
$P_u \cong C_0 / 8.2$	roller bearing	[N]	[5.32]
P_u	fatigue limit load	[N]	

Contamination coefficient

Hard and firm contaminants that are present in the lubricant can lead to lasting impressions being made in the raceways during the rolling-over process. Local stress peaks caused by over rolling the contaminations reduce the life time of the high precision rolling bearings. A reduction in life time due to hard particles will depend on the size of the bearing, the lubricant film thickness (viscosity ratio κ) and on the size, type, hardness and number of particles. Other sorts of contamination, like the inflow of fluids, cannot, however, be considered in connection with this coefficient.

If severe contamination occurs ($e_c \rightarrow 0$), failure due to wear will become a likelihood. The actual life time will then be much shorter than the calculated life time.

Level of contamination	Coefficient e_c	
	$D_{pw} < 100$ mm	$D_{pw} > 100$ mm
Extreme cleanliness Particle size same as lubricant film thickness, laboratory conditions	1	1
High cleanliness Extra-fine filtering of oil feeding, sealed, greased bearings	0.8...0.6	0.9...0.8
Normal cleanliness Fine filtering of oil feeding, greased bearings with shields	0.6...0.5	0.8...0.6
Light contamination Light contaminations in oil feeding	0.5...0.3	0.6...0.4
Moderate contamination Bearing is contaminated with abrasion from other machine components	0.3...0.1	0.4...0.2
Severe contamination Heavily polluted bearing ambience, inadequate sealing	0.1...0	0.1...0
Very severe contamination	0	0

Table 5.5: Contamination coefficients e_c

Viscosity ratio

The viscosity ratio κ is used to rate the quality of the lubricant film formation. It defines the ratio of lubricant viscosity ν at operating temperature to the reference viscosity ν_1 . With $\kappa = 1$, the separative lubricant film will be exactly achieved. Procedural method: with the help of diagram 5.1 initially determine the reference viscosity ν_1 subject to the reference diameter D_{pw} and the speed n .

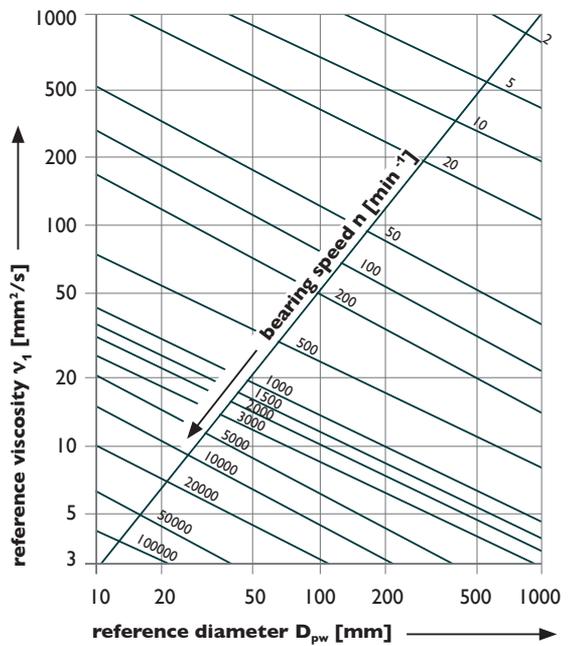

Diagram 5.1: Required kinematic viscosity ν_1

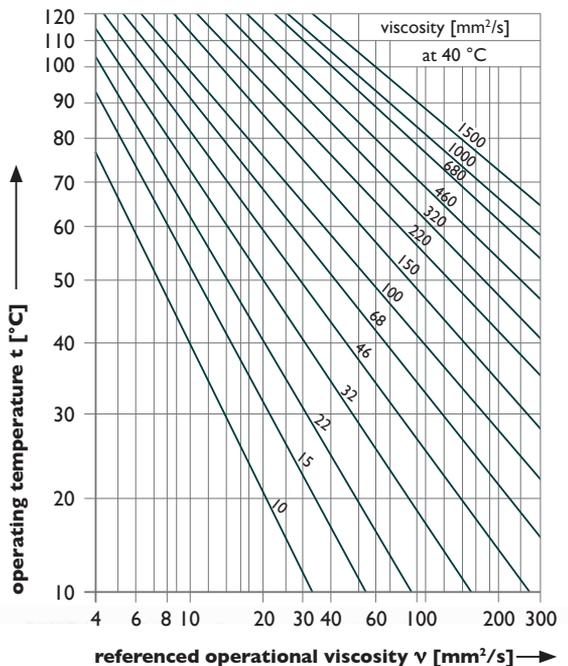

Diagram 5.2: Viscosity at operating temperature for mineral oils

From diagram 5.2, relating to viscosity and temperature, the referenced operational viscosity ν is then read off below the point at which the anticipated operating temperature t intersects with the diagonal graph of the reference viscosities at 40 °C.

From this, the viscosity ratio κ is then established:

$$\kappa = \frac{\nu}{\nu_1} \quad [5.33]$$

κ	viscosity ratio	
ν	referenced operational viscosity	[mm ² /s]
ν_1	reference viscosity	[mm ² /s]

In the mixed friction range $\kappa < 1$, higher values may be achieved with the help of suitable additives: Wear can be reduced, corrosion be counteracted, friction reduced and the adhesion of the lubricant in the lubrication gaps improved with the help of special additives like solids, or polar and/or polymer active substances.

Additives should be used if the referenced operational viscosity for ball bearings is $< 13 \text{ mm}^2/\text{s}$, if it is $< 20 \text{ mm}^2/\text{s}$ for roller bearings, and if the basic speed rating is relatively low, at $d_m \cdot n < 10,000$.

The viscosity ratio κ , in accordance with equation 5.33, is determined by means of diagrams 5.1 and 5.2; but it may also be calculated.

The following is valid for the reference viscosity ν_1 :

$$\nu_1 = 45000 \cdot n^{-0.83} \cdot D_{pw}^{-0.5} \quad \text{for } n < 1000 \text{ min}^{-1} \quad [5.34]$$

$$\nu_1 = 4500 \cdot n^{-0.5} \cdot D_{pw}^{-0.5} \quad \text{for } n > 1000 \text{ min}^{-1} \quad [5.35]$$

D_{pw} reference diameter of the high precision rolling bearing
 $= d_m = (d + D) / 2$ [mm]

For lubricants with a density that deviates from the reference density of $\rho_1 = 0.89 \text{ g/cm}^3$ at 20 °C the following formula applies:

$$\kappa = \frac{\nu}{\nu_1} \cdot \left(\frac{\rho}{\rho_1} \right)^{0.83} \quad [5.36]$$

ρ	density of lubricant used	[g/cm ³]
ρ_1	reference density	[g/cm ³]

For a viscosity ratio $\kappa < 1$ and a contamination coefficient $e_c > 0.2$ the value $\kappa = 1$ in calculations can be used, if a lubricant with active EP additives is used. The life cycle coefficient must then, however, be limited to $a_{DIN} < 3$. In the case of severe contamination ($e_c < 0.2$) the effectiveness of the use of additives must be demonstrated.

The determining of the value a_{DIN} for IBC high precision angular contact ball bearings and IBC high precision cylindrical roller bearings by graph and by calculation is summarised on the following page.

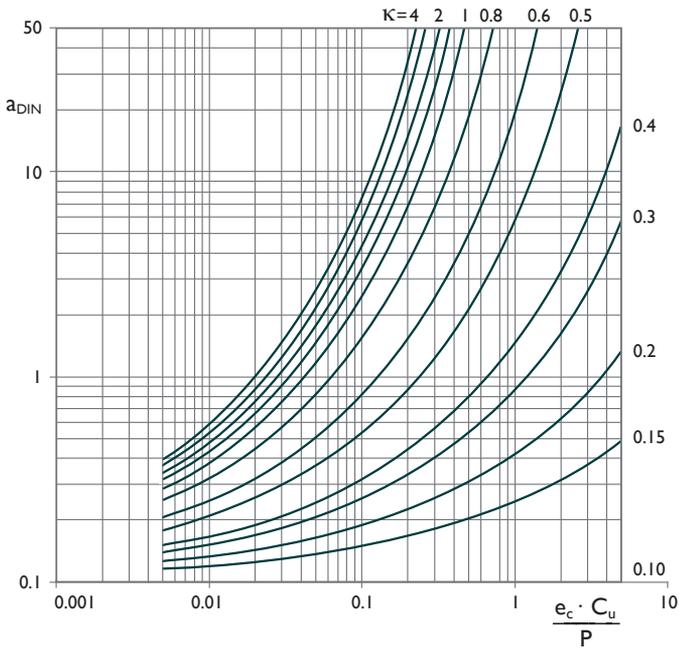

Diagram 5.3: Life cycle coefficient a_{DIN} for IBC high precision angular contact ball bearings

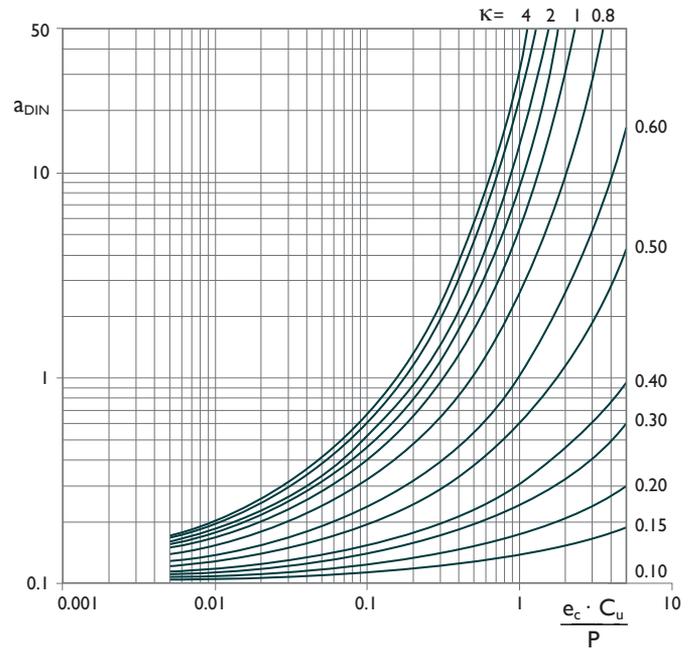

Diagram 5.4: Life cycle coefficient a_{DIN} for IBC high precision cylindrical roller bearings

Calculation rule for a_{DIN} for IBC High precision angular contact ball bearings:

$$a_{DIN} = 0.1 \cdot \left[1 - \left(2.56705 - \frac{2.26492}{\kappa^{0.0543806}} \cdot \left(\frac{e_c \cdot C_u}{P} \right)^{\frac{1}{3}} \right)^{-9.3} \right] \quad \text{for } 0,1 \leq \kappa < 0,4 \quad [5.37]$$

$$a_{DIN} = 0.1 \cdot \left[1 - \left(2.56705 - \frac{1.99866}{\kappa^{0.190870}} \cdot \left(\frac{e_c \cdot C_u}{P} \right)^{\frac{1}{3}} \right)^{-9.3} \right] \quad \text{for } 0,4 \leq \kappa < 1 \quad [5.38]$$

$$a_{DIN} = 0.1 \cdot \left[1 - \left(2.56705 - \frac{1.99866}{\kappa^{0.0717391}} \cdot \left(\frac{e_c \cdot C_u}{P} \right)^{\frac{1}{3}} \right)^{-9.3} \right] \quad \text{for } 1 \leq \kappa \leq 4 \quad [5.39]$$

Calculation rule for a_{DIN} for IBC High precision cylindrical roller bearings:

$$a_{DIN} = 0.1 \cdot \left[1 - \left(1.58592 - \frac{1.39926}{\kappa^{0.0543806}} \cdot \left(\frac{e_c \cdot C_u}{P} \right)^{0.4} \right)^{-9,185} \right] \quad \text{for } 0,1 \leq \kappa < 0,4 \quad [5.40]$$

$$a_{DIN} = 0.1 \cdot \left[1 - \left(1.58592 - \frac{1.23477}{\kappa^{0.190870}} \cdot \left(\frac{e_c \cdot C_u}{P} \right)^{0.4} \right)^{-9,185} \right] \quad \text{for } 0,4 \leq \kappa < 1 \quad [5.41]$$

$$a_{DIN} = 0.1 \cdot \left[1 - \left(1.58592 - \frac{1.23477}{\kappa^{0.0717391}} \cdot \left(\frac{e_c \cdot C_u}{P} \right)^{0.4} \right)^{-9,185} \right] \quad \text{for } 1 \leq \kappa \leq 4 \quad [5.42]$$

5.3 IBC-specific factors

For options that exceed the expanded life time calculation according to DIN ISO 281, IBC has defined further factors that lead to a different life time and that may be taken into account optionally. These factors are assumed under “material-related factors” a_{lb} and a_{wk} .

The factor a_{tr} recognises the positive characteristics of the ATCoat coating if the coating is applied to the raceways. (This type of coating may also be applied solely to the outer diameter in order to eliminate fretting corrosion to the rolling bearing); see Chapter 9 (Materials).

The factor a_{wk} makes reference to the material of the rolling elements and takes into account the considerably longer life time of ceramic rolling elements; there are several reasons for this.

Material-related factors			
Track material	a_{lb}	Rolling element material	a_{wk}
uncoated	1.00	100Cr6	1.0
IR ATCoat	1.15	Si ₃ N ₄	2.0
OR ATCoat	1.05		
IR & OR ATCoat	1.20		

Table 5.6: Coefficients a_{lb} and a_{wk}

When using rolling bearings that have been thermally treated to a higher degree, all components used must be matched to the continuous operation temperature.

The IBC-specific factors enter into the calculation of the expanded life time in multiplicative form:

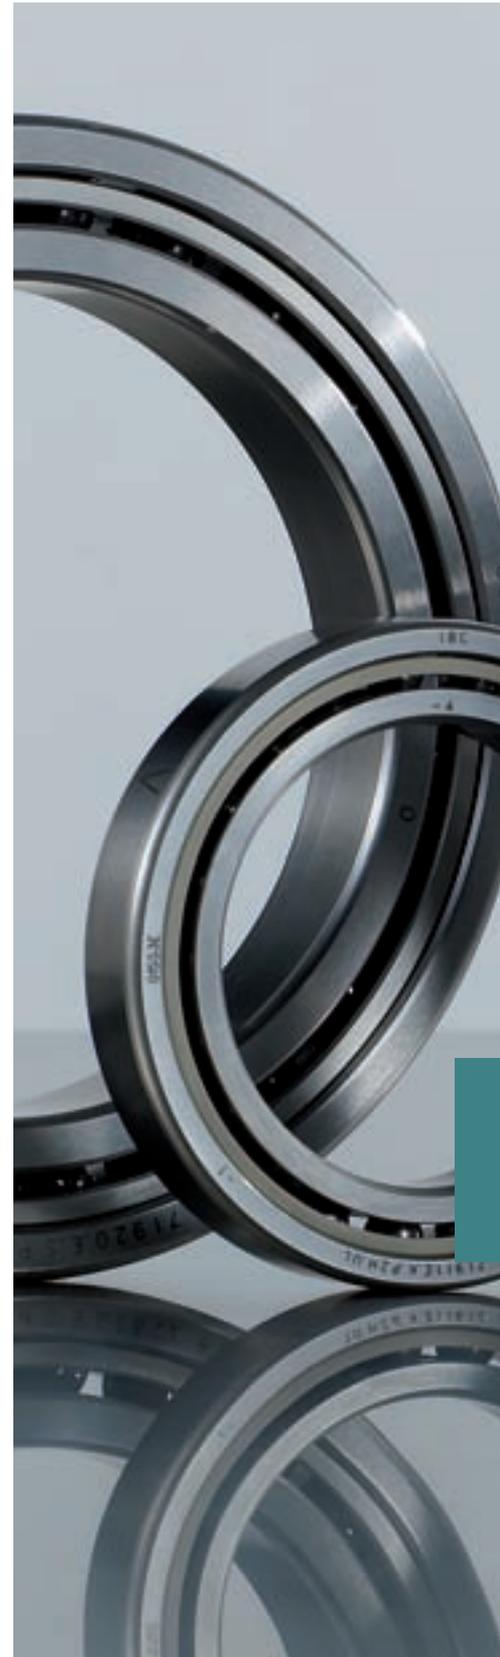

$$L_{10,erw,IBC} = a_{lb} \cdot a_{wk} \cdot L_{10,nm} \quad [h] \quad [5.43]$$

$L_{10,erw,IBC}$ IBC-specific modified life time [h]

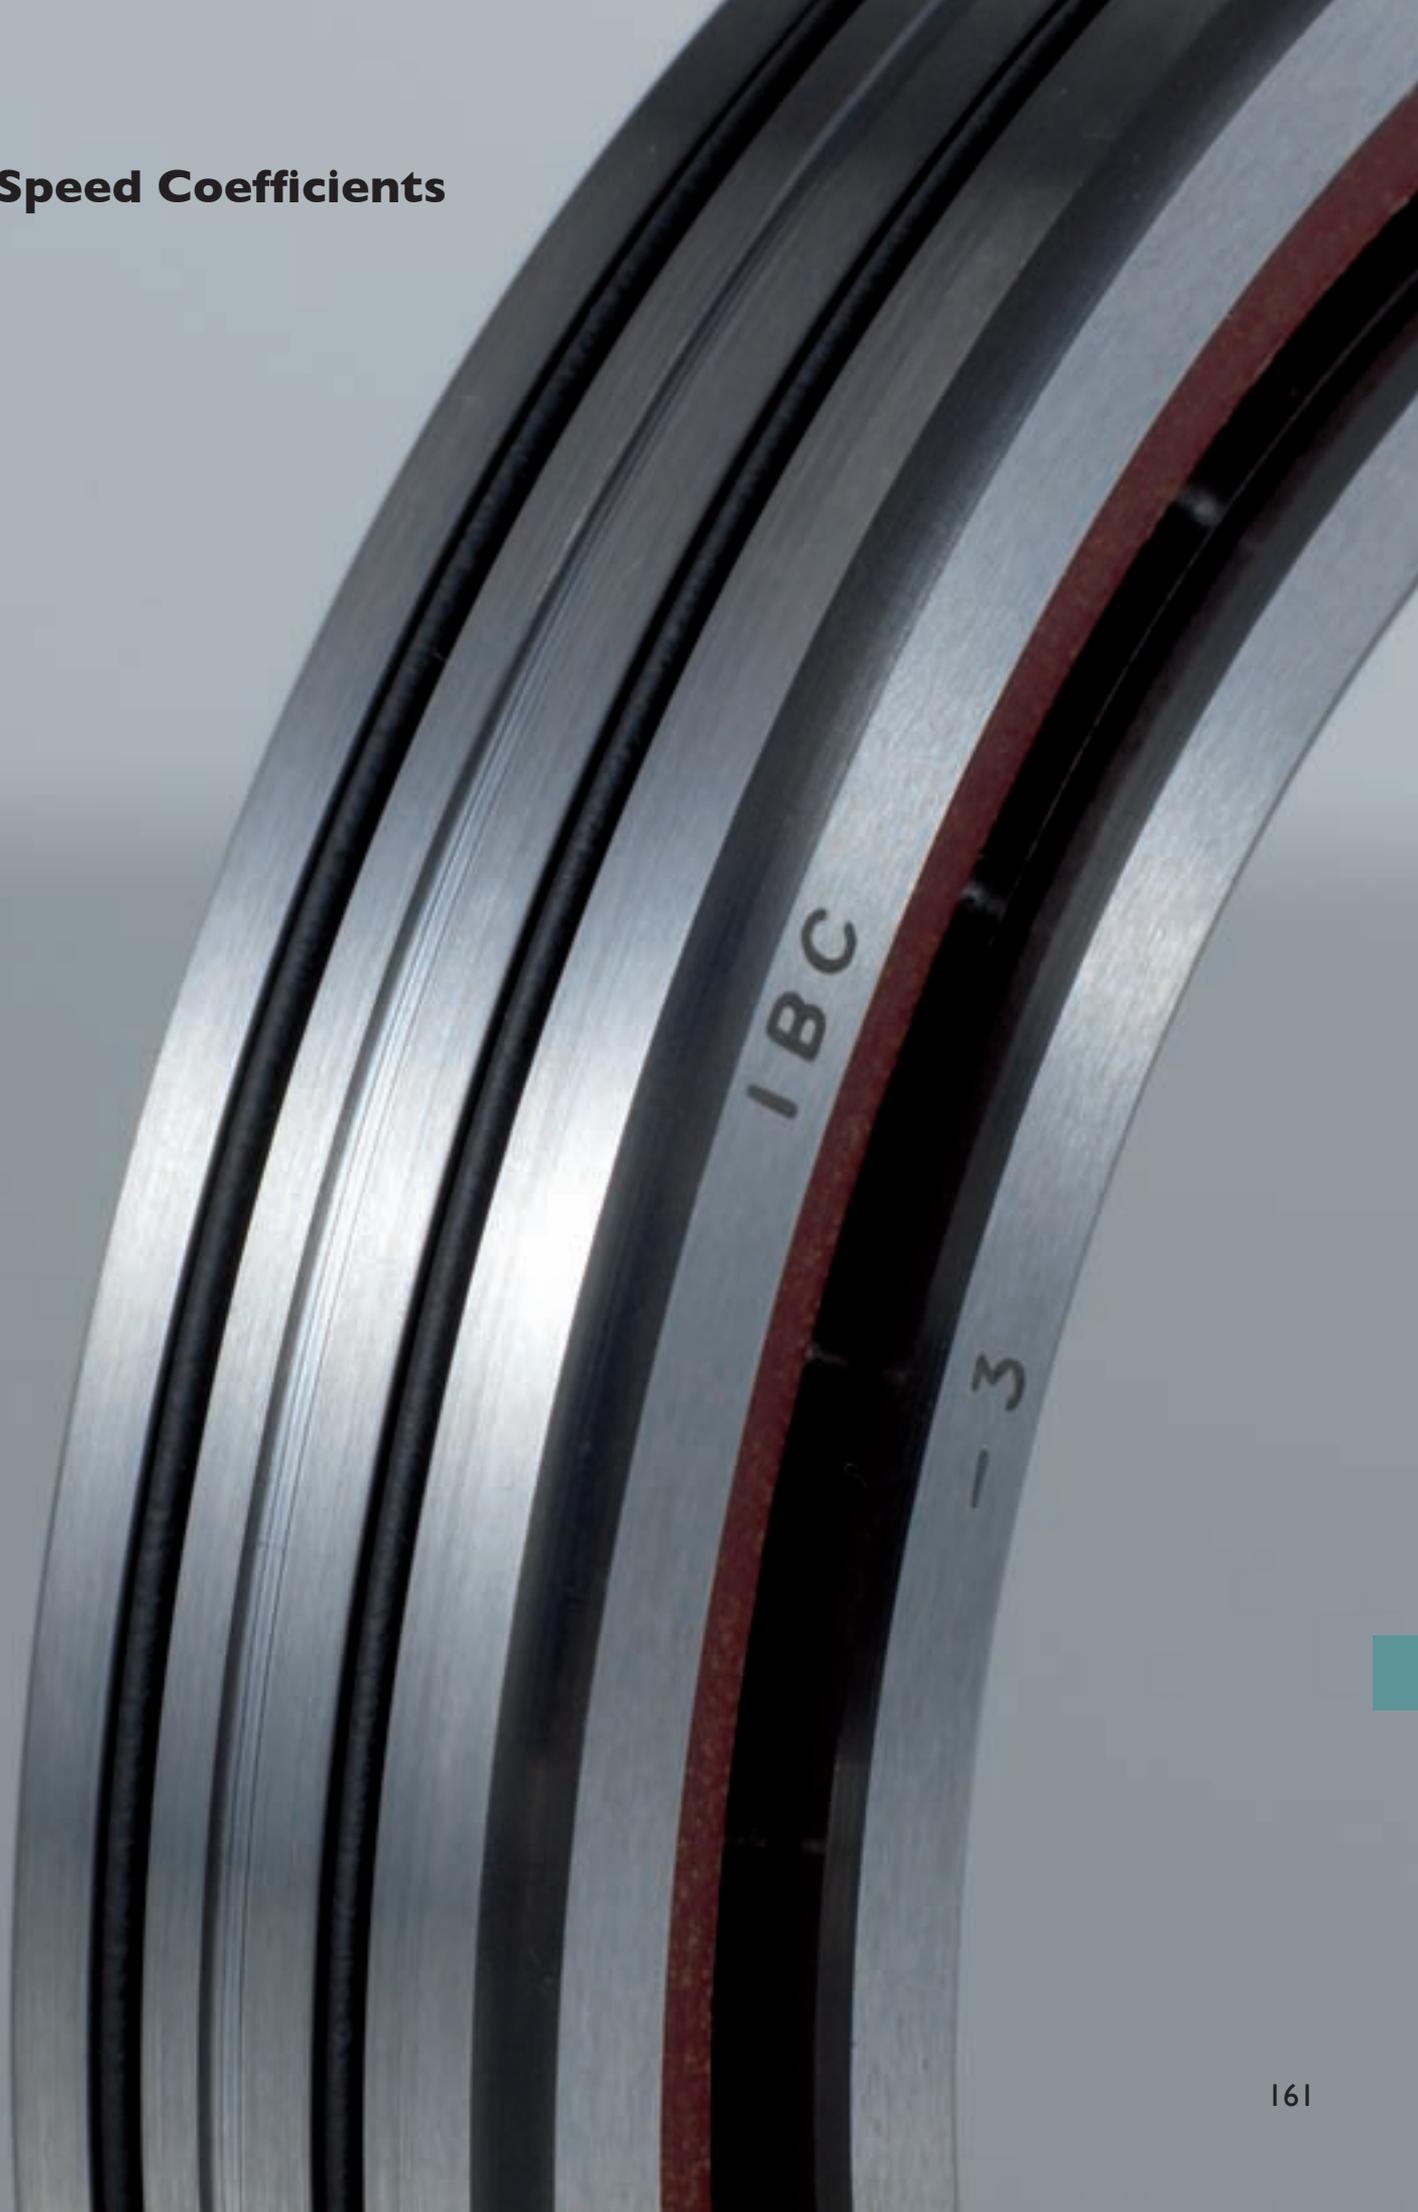

a_{lb}, a_{wk} material-related factors

$L_{10,nm}$ modified life time [h]

In addition, the life time of the grease should be compared to the calculated life time of the high precision rolling bearings in order to ascertain if permanent lubrication is an option, or in order to develop a strategy for continuous or cyclical re-lubrication.

6. Speed Coefficients

6. Speed coefficients

Under defined conditions, the maximum obtainable operating speed depends on a number of different factors. Most of these factors are numerically known within certain tolerances. For new applications, however, they must be determined and/or optimised with the help of tests.

The maximum attainable operating speed is achieved with a single bearing that is slightly preloaded with springs, has a load of $P \leq 0.06 \cdot C$ and has good heat dissipation.

The operating speed is based on the basic speed rating n for a single high precision rolling bearing that is specified in the respective part of the table. The maximum attainable operating speed is calculated by multiplying the basic speed rating specified in the bearing tables with the speed coefficients mentioned below.

$$N_B = n \cdot n_{av} \cdot n_f \cdot n_k \cdot n_j \cdot n_o \cdot n_r \quad [\text{min}^{-1}] \quad [6.1]$$

N_B	operating speed	$[\text{min}^{-1}]$
n	basic speed rating	$[\text{min}^{-1}]$
n_{av}	speed coefficient for preload and/or arrangement	
n_f	load-dependent speed coefficient	
n_k	cage coefficient	
n_j	speed coefficient of lubricant	
n_o	speed coefficient of surface plating	
n_r	kinematic rolling coefficient	

Basic speed rating

This parameter is to be taken from the bearing tables, depending on the type of lubricant (grease or oil).

Speed coefficient for preload and arrangement

Reduced limiting speeds apply to high precision rolling bearings that are set against each other in an arrangement; these limiting speeds may be determined with the aid of the speed coefficients contained in the following table.

Bearing arrangement	Preload			
	X	L	M	H
< >	1.00	1.00	0.90	0.70
<< >	0.95	0.90	0.80	0.60
<< >>	1.00	0.95	0.85	0.65
<> <>	0.95	0.85	0.75	0.60
<<> <>	0.80	0.70	0.55	0.50
<<>> <>	0.70	0.60	0.50	0.40

Table 6.1: Speed coefficients for preloading

The following speed coefficients apply to balanced IBC high precision angular contact ball bearing sets:

Preload combination			Speed coefficient	Preload combination				Speed coefficient
X	X	L	0.90	X	X	X	M	0.65
L	L	M	0.85	L	L	L	H	0.60
M	M	H	0.60					

Table 6.2: Speed coefficient for preload combinations

Vertical shaft arrangement

For vertically arranged shafts, the values mentioned in the table above must be additionally multiplied by factor 0.8, because of the unfavourable lubrication condition and the altered cage guidance.

Load-dependent speed coefficient

The operating speed must be reduced for higher equivalent bearing loads. Diagram 6.1 is used to determine the load-dependent speed coefficient.

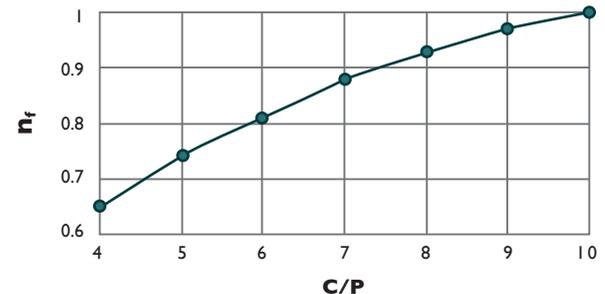

Diagram 6.1: Load-dependent speed coefficient

Cage coefficient

As standard, high precision angular contact ball bearings and high precision cylindrical roller bearings are fitted with cages that allow for the highest rotational speeds. Alternative cage materials may limit the attainable speed. Please consult our technical service teams to find a solution to your special bearing requirements.

Speed coefficient of lubricant

If a grease filling quantity is used that deviates from the standard quantity, and if greases with an especially high or low viscosity are used, this will result in modified factors for the grease lubrication's basic speed rating.

The grease quantities for the standard greasing that is carried out in the factory are specified in table 7.2 in Chapter 7 (Lubrication) with reference to each bearing type.

The speed coefficients for the various greases are also specified in Chapter 7 (Lubrication), in this case in table 7.1.

Speed coefficient of ATCoat coating

Depending on the combination of coated and/or uncoated rings, marked with the designation A11, A15, A21 and A31 (see designation systems), the following coefficients may be taken into account:

A11	A15	A21	A31
1.20	1.20	1.15	1.05

Table 6.3: Speed coefficient depending on the application of the ATCoat coating

An adapted grease distribution run will take account of the significantly altered rolling motion conditions prevalent in ATCoat coated rolling bearing rings.

Kinematic rolling coefficient

The basic speed rating of high precision rolling bearings to be found in the tables applies to the rotating inner ring with a kinematic rolling coefficient of 1; for a rotating outer ring the kinematic rolling coefficient is 0.6.

Optimised spring preload

The centrifugal force acting on the rolling elements influences the contact angle of the inner and the outer ring in different ways. Whereas the centrifugal force tries to pull the rolling elements into the centre of the raceway with reference to the outer ring, and thereby tries to reduce the contact angle, the rolling elements simultaneously rise towards the shoulder of the inner ring and thereby widen the contact angle. The result is a bore-rolling effect that encourages wear. An adapted spring preload may be used to counteract the rising up of the rolling elements at the inner ring.

The dependencies that are used to calculate the ideal spring preload are determined by means of the following formula:

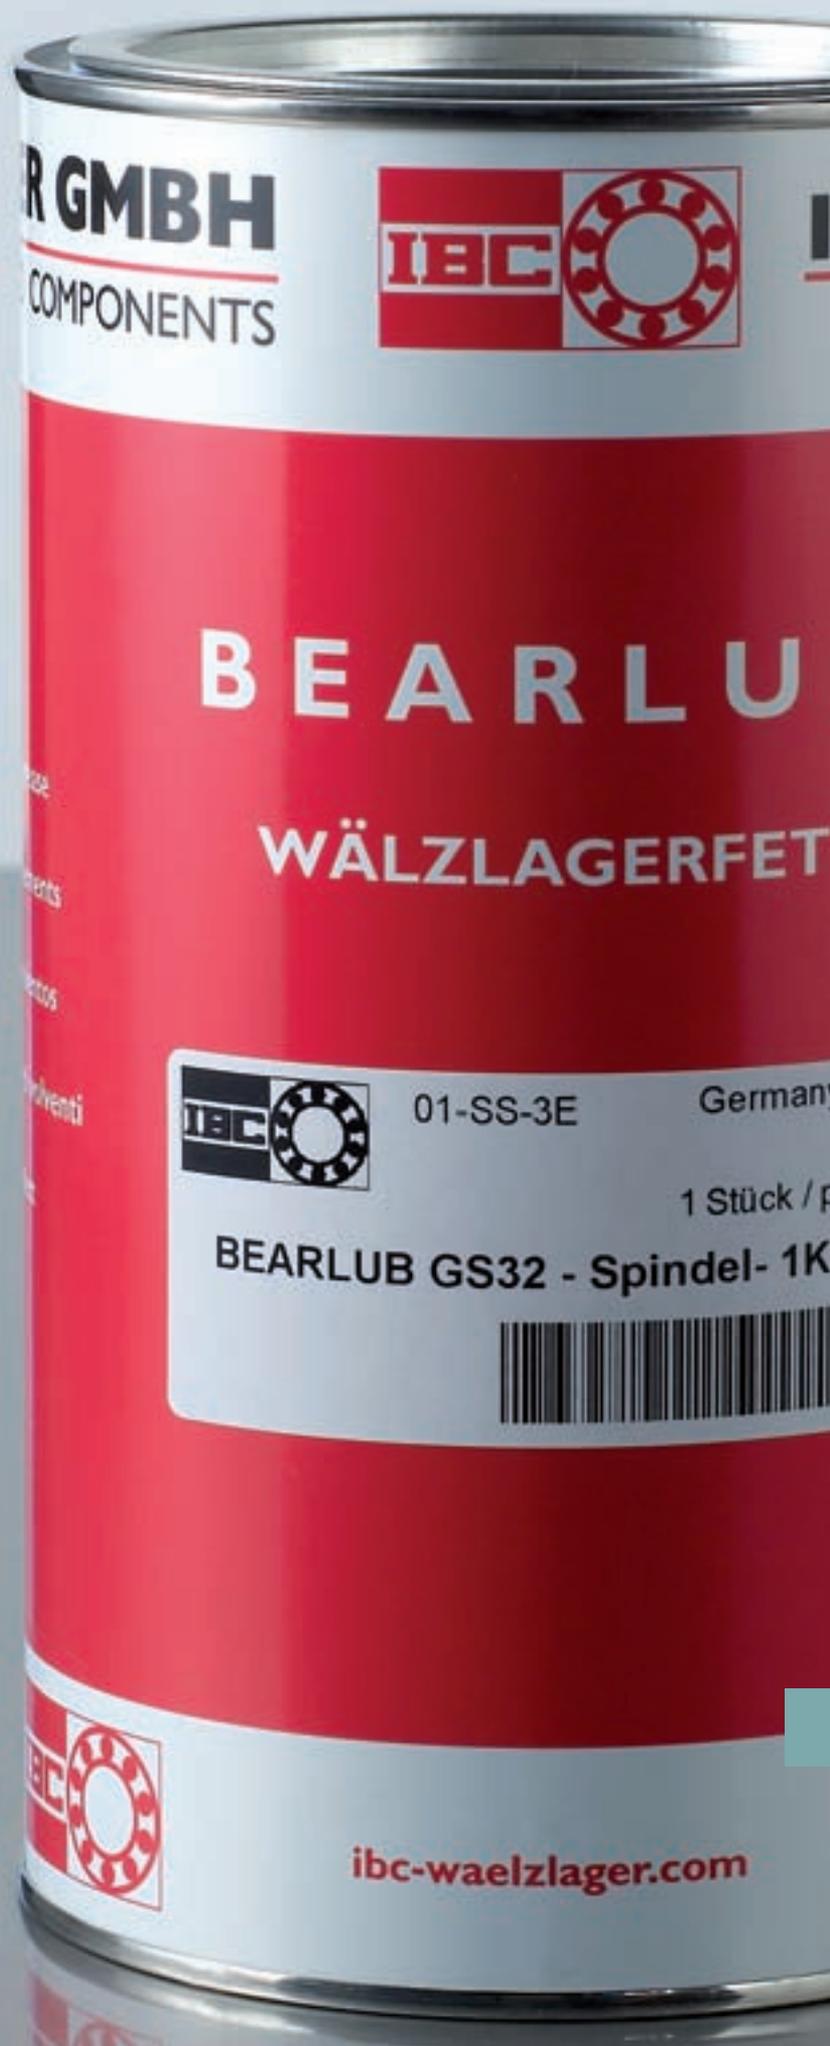

$$F_{\text{Feder}} = k \cdot C_0^2 \cdot n_{\text{max}}^2 \cdot 10^{-15} \quad [\text{N}] \quad [6.2]$$

F_{Feder}	spring preload	[N]
k	contact angle dependant constant	
	$k = 6.5$ contact angle 15°	
	$k = 13$ contact angle 25°	
	$k = 17$ contact angle 30°	
C_0	static load rating	[N]
n_{max}	maximum service speed	[min ⁻¹]

Only very seldom can the preload of a mounted spindle be adjusted later on. Therefore a compromise needs to be achieved in determining the preload, with the aim of guaranteeing operational safety for a variety of speed ranges.

7. Lubrication

7. Lubrication

The choice of the right lubricant has a very great impact on the operational safety of precision bearings, because lubricants reduce friction and wear. The majority of rolling bearings that do not reach their scheduled life time fail because of faulty lubrication.

The following influential factors need to be taken into account:

- rotational speed
- service temperature range
- fatigue
- the load ratio C/P
- the minimum required viscosity ν_1 with reference to the mean bearing diameter
- the lubricant condition κ
- EP additives
- water resistance
- corrosion protection
- noise generation

IBC has a wide range of high-quality greases in stock that are suited to the various kinds of requirements. High precision rolling bearings that are ready-greased during manufacture can be ordered from IBC by specifying the relevant suffix. For such high precision rolling bearings, the only thing the customer needs to do is to carry out the grease distribution run.

Should you require any of these greases for service or pre-assembly, you can order them from IBC in tubes or tins, or in even bigger containers, with the aid of the following order system:

GH76-400	400 g tube of grease GH76
GH62-1000	1 kg tin of grease GH62

Grease lubrication for rolling bearings

Grease lubrication is the easiest and therefore the most cost-efficient form of lubrication. It is used for the majority of all rolling bearings. Lithium soap greases with mineral basic oil that are of comparatively high viscosity are predominantly used for standard deep groove ball bearings. For high-speed applications, on the

other hand, special greases are used, because the synthetic oils and special thickening agents they contain allow for much higher speed coefficients, not least because of their lower viscosity. The greases with the designation GS, or GH for higher temperatures, are especially suitable for high precision rolling bearing applications.

IBC designation	Speed coefficient $d_m \cdot n \cdot 10^{-6}$ mm/min	Temperature range ΔT °C	NLGI Consistency Class	Base oil	Viscosity of base oil		Thickener	Density ρ g/cm ³	Note
					40 °C	100 °C			
GS 32	1.0	-50 / +120	2	mineral oil + ester oil	15	3.7	lithium soap	0.88	light, noise-tested grease for high rotational speeds and low temperatures
GS 34	1.0	-50 / +120	2	mineral oil + ester oil	21	4.7	barium complex	0.99	high speed and low temperature grease
GS 36	1.8	-40 / +120	2/3	PAO ester	25	6	lithium special soap	0.94	special grease for high-speed spindle bearings in machine tools
GS 41	1.0	-60 / +140	2	SK synthetic oil	18	4	barium complex soap	0.96	high-speed grease, especially suitable for use with tapered roller bearings
GS 75	>2.0	-50 / +120	2	ester oil + SKW	22	5	polyurea	0.92	special grease for high-speed spindle bearings in machine tools
GH 60	0.5	-30 / +175	2	paraffin base	116	12.3	synthetic polyurea	0.98	Used with high-moisture and noise sensitive applications
GH 62	0.5	-30 / +160	2/3	ester oil + SKW	150	18	polyurea	0.88	high-temperature and long-term lubrication grease
GH 68	1.3	-35 / +160	2	ester oil	55	9	lithium soap	0.98	lubrication grease for high temperatures, loads and rotational speeds
GH 70	0.6	-40 / +180	2/3	synthetic oil	70	9.4	polyurea	0.95	very low-noise high temperature grease
GH 72	0.7	-40 / +180	2/3	ester oil	100	12	polyurea	0.97	low-noise, used for for-life lubrication at high temperatures, good corrosion protection
GH 76	1.1	-50 / +150	2	ester oil	18	5	lithium soap	0.96	good noise behaviour, overall low friction, for small and medium bearings
GH 83	0.3	-60 / +250	1	fluorinated polyester oil	300	85	PTFE	1.94	highest service viscosity at very high operation temperatures
GH 88	0.3	-30 / +260	2	perfluorinated polyether	55	9	PU	1.70	high thermal durability, resistant to pressure, vacuum, radiation and media
GH 90	0.6	-50 / +260	2	perfluorinated polyether	190	34	PTFE	1.90	long life time, broad elastomer compatibility; stable with regard to aggressive media
GA 91	0.3	-75 / +260	1/2	silicone oil	55	14	Teflon	1.33	resistant to water; corrosion and oxidation, used in the aviation industry
GF 20	0.3	-40 / +120	1	mineral oil	230	22	aluminium complex soap	0.90	good adhesive power and wear protection, used in the food technology sector

Table 7.2: IBC grease quantity table for standard lubrication

Grease quantity

The quantity of grease used in a rolling bearing depends on the speed coefficient $d_m \cdot n$, the grease running-in time, the grease service life and possibly also on additional protection being used against external contamination in the case of slow-running rolling bearings.

The speed requirements for machine tool spindles have been on the increase in many areas over the past few years. Thus, the quantity of grease has been adjusted and reduced in order to take account of this development, and the grease distribution run may therefore be shortened, running until a deposit of grease has formed on the sides of the raceways

The improved lubricant quantities also have a positive influence on the flexibility in operation of the bearing. The IBC standard grease quantity is designed to meet these requirements.

Apart from the absolute quantity of grease, the right pre-treatment of the high precision rolling bearing and the insertion of the lubricant in the right place are especially important for the lubricating process. It is essential, therefore, to take the following considerations into account:

It is better to distribute the quantity of grease evenly by means of a syringe, for instance, than to insert the grease with a spatula. In the case of cages guided on the outer ring, important places for greasing are the contact surfaces between the cage and the outer ring of the bearing; other important places are the raceway area and especially the gaps in the rolling element cage.

If requirements for service speed are low, which means limited flexibility is required of the bearing, a significantly higher quantity of grease may be used than the standard quantity. Conversely, the grease quantity should be significantly reduced for very high speed coefficients. In extreme cases this can lead to the free bearing space receiving a 10% lubrication fill.

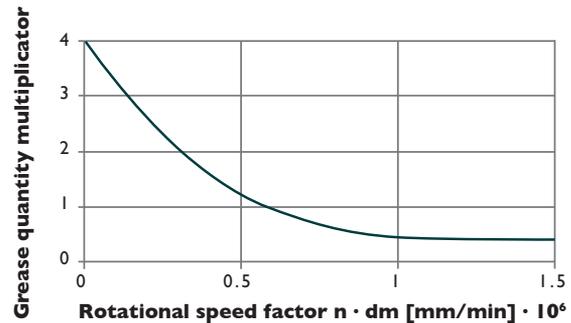

Diagram 7.1: Factor for grease quantity over rotational speed factor

Diagram 7.1 shows the increase factor for the grease quantity compared to the 25% standard grease quantity that is used for IBC high precision angular contact ball bearings. The factor ranges from full lubrication for very low speeds to minimum lubrication for very high speeds. IBC high precision cylindrical roller bearings have a default grease quantity of 10%, which means that the factor given in diagram 7.1 cannot be applied to cylindrical roller bearings.

A further reduction in lubricant quantity may be achieved with the help of dispersion lubrication. This kind of lubrication entails dipping the high precision rolling bearing in an emulsion of solvent with 3–5% grease; the inner ring is turned against the outer ring, and then the bearing is dried. This procedure ensures that all parts of the high precision rolling bearing are coated in lubricant. Dispersion lubrication may also be used as a basis for subsequent normal lubrication.

Grease distribution run

A grease distribution run should be carried out before bringing high precision rolling bearings into service; if possible this running-in should include temperature monitoring.

Different scenarios for the grease distribution run have been proven and tested; they do, however, depend on the test stand used. In high precision rolling bearings that are firmly preloaded against each other, the preload may accidentally and significantly increase during the grease distribution run due to thermal expansion of the inner ring. During the first few minutes of the running-in process, or after restarting with a cold spindle, the inner ring will heat considerably faster and therefore expand more than the outer ring. For a short period of time, the preload will therefore increase, sometimes to an extreme degree, until temperature balance is regained via heat transfer to the outer ring.

This effect is especially critical for bearings in an X-arrangement. It also applies to hybrid bearings, because although their ceramic

rolling elements have a smaller coefficient of expansion, they also have reduced thermal conductivity and higher stiffness. Spring preloaded bearing arrangements place slightly fewer demands on the grease distribution run. Due to the axial flexibility of the spring adjustment, they are able to compensate for the deformation of the inner ring.

Provided that a fixed speed is used, the heat generated may be controlled via the ratio of duty cycles to rest periods, whereby the former are extended by degrees and the latter shortened, until steady temperature conditions exist for continuous operation. During this process, cooling phases should always be introduced as soon as the maximum temperature of 60-70 °C is reached. There will come a point at which the temperature steadies, as soon as the excess grease has been displaced from the raceway, but it will then slowly start to fall. The schedule to be found in diagram 7.2 is well established in practice.

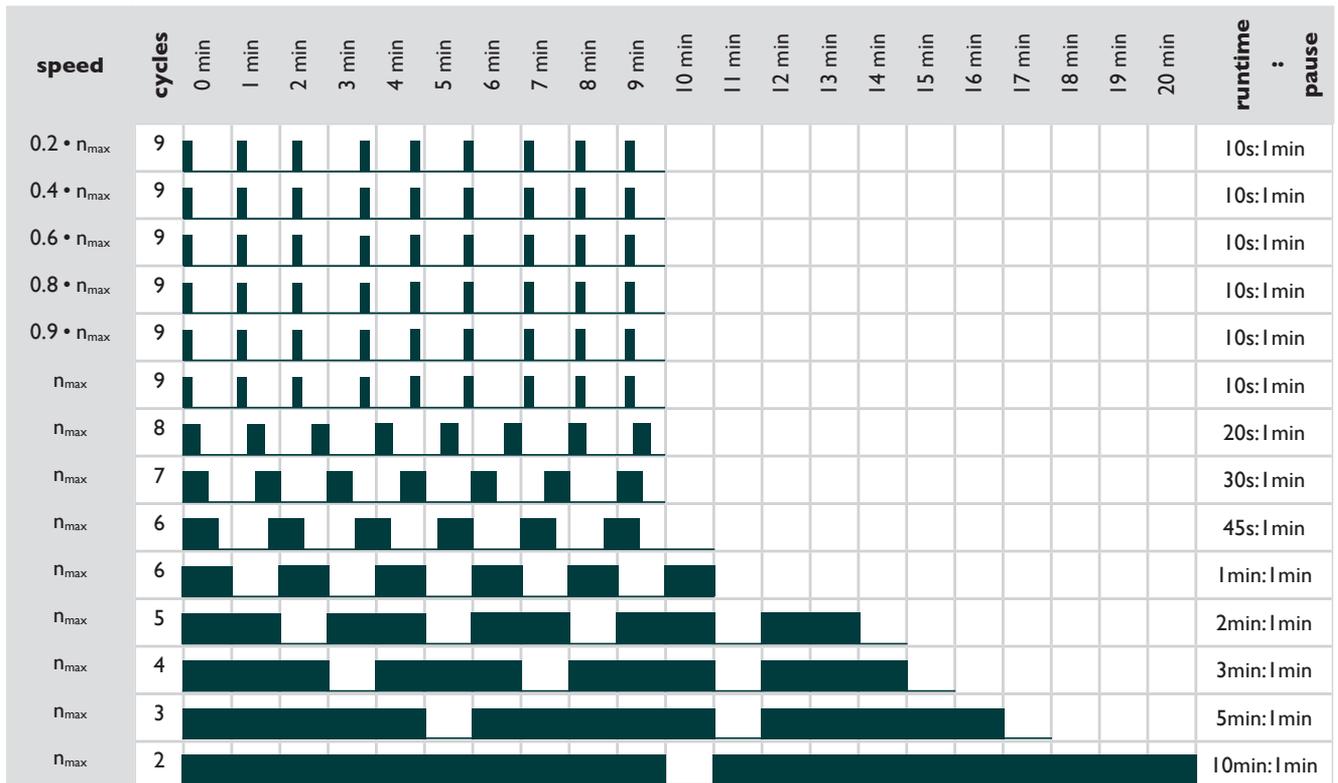

Diagram 7.2: Progressive running-in with repeated short runs, followed by longer periods at maximum speed

Grease life time

Grease life time or grease service life depends on a number of parameters; it may approximately be calculated according to standard DIN 51825 in the following way:

$$t_{rq} = q \cdot t_f \quad [7.1]$$

t_{rq} practical grease life time [h]
 q overall reduction factor
 t_f unreduced grease life time [h]

$$q = f_1 \cdot f_2 \cdot f_3 \cdot f_4 \cdot f_5 \cdot f_6 \cdot \dots \text{reduction factors} \quad [7.2]$$

f_1 influence of ambient media (0.1...0.9)
 f_2 influence of dynamics, shocks (0.1...0.9)
 f_3 influence of bearing temperature (0.1...0.9)
 f_4 influence of bearing stress (0.1...1.0)
 f_5 influence of air flow (0.1...0.7)
 f_6 influence of type of mounting (0.5...0.7)

$$t_f = f(k_f \cdot n \cdot d_m) \text{ for example from figure 7.3} \quad [7.3]$$

k_f rolling bearing design factor
 1.6...2.0 for high precision angular contact ball bearings
 3.0...3.5 for high precision cylindrical roller bearings
 n service speed [min⁻¹]
 d_m mean rolling bearing diameter $(d + D) / 2$ [mm]

The grease life time may be extracted from the lubricant data sheet that the manufacturer in question supplies.

First of all, the factor $k_f \cdot n \cdot d_m$ is calculated for this process. Above the resulting value, and at the level of the graph for the relevant operating temperature, the grease life time is then read off from the diagram below.

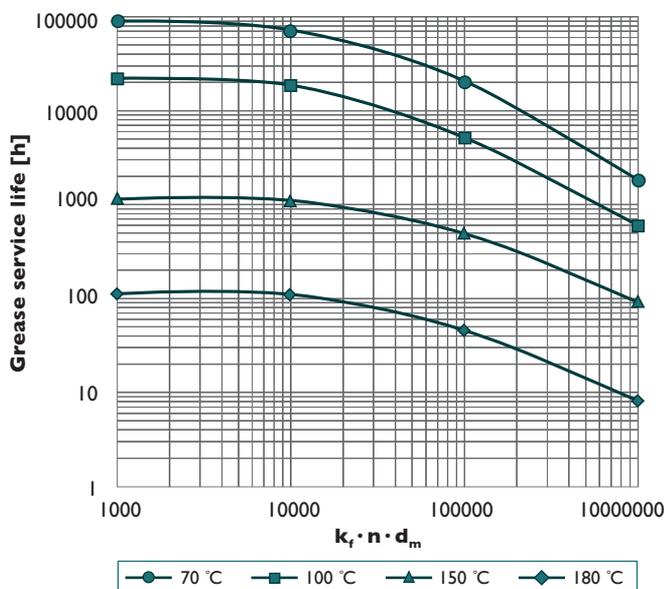

Diagram 7.3: Example of a grease diagram

The grease life time is a theoretical value that is subject to further influencing factors; these factors may further limit the service life of the grease.

Ambient media		
moisture and dust on the raceways		
f_1 (moderate)		0.7...0.9
f_1 (strong)		0.4...0.7
f_1 (excessive)		0.1...0.4
Dynamics		
shocks, vibrations and oscillation		
f_2 (moderate)		0.7...0.9
f_2 (strong)		0.4...0.7
f_2 (very strong)		0.1...0.4
Operating temperature		
f_3 from the relevant grease data sheet		
Bearing stress		
f_4 (moderate)	$C/P > 20$	1.0
f_4 (medium)	$C/P > 10$	0.7
f_4 (average)	$C/P > 8$	0.5
f_4 (strong)	$C/P > 5$	0.3
f_4 (very strong)	$C/P > 2$	0.2
f_4 (exceedingly strong)	$C/P > 1$	0.1
Air flow through bearing		
f_5 (moderate)		
f_5 (strong)		0.1...0.5
Mounting situation		
f_6 (rotating outer ring)		
f_6 (vertical shaft)		0.5...0.9
Further reduction factors		
f_7 (viscosity ratio κ)		
f_8 (single row cylindrical roller bearing)		0.63
f_8 (double row cylindrical roller bearing)		0.3
f_8 (full complement cylindrical roller bearing)		0.04
f_9 (hybrid bearing)		2.5...3.5

Table 7.3: Reduction factors for grease service life

Re-lubrication

In most cases, for-life grease lubrication is the option of choice. If multiple reduction factors limit grease life time, however, provision must be made for the option of re-lubricating the high precision rolling bearing.

A suitably short re-lubricating period must apply in very adverse lubrication conditions. If this is not feasible, the high precision rolling bearings must be replaced in the context of planned maintenance, taking into account the above mentioned factors.

In some cases, automatic re-lubricating systems may be used, that continuously dispense minimal and fixed amounts of grease. High precision angular contact ball bearings with a lubrication facility in the outer ring (S) may also be suitable for this procedure. In certain cases, the lubrication holes must be adjusted to suit the viscosity of the grease.

In the case of fast-running rolling bearings, higher temperatures should be anticipated directly after re-lubricating. Depending on the method of insertion, the newly inserted lubricant first needs to be displaced from the contact area of the rolling elements to the raceways. If necessary, a new grease distribution run may have to be carried out.

Oil/air lubrication

This lubrication system is used to increase speed and operational safety. A minimum quantity of oil is mixed in a fixed ratio with compressed air in an oil/air lubrication unit; this mixture is then finely metered and fed to the bearing as per unit of time.

The oil/air jet lubrication for high precision rolling bearings with cages guided on the outer ring is carried out between the cage and the inner ring at the injection diameter D_{pi} via a small nozzle that is either directed in parallel into the gap or is slightly tilted towards the inner ring. The latter method additionally helps to cool the inner ring – the component that is most exposed to heat.

For each oil jet lubrication ring a nozzle measuring 1 mm to 1.5 mm in diameter and roughly five times the length of the bore diameter is recommended.

High precision rolling bearings that are lubricated via the outer ring present an alternative to this system. In this case, the outer ring of the bearing possesses a radially circumferential supply groove that is surrounded by two O-rings for sealing and at least one supply hole. These high precision rolling bearings are identified by an S after the contact angle designation.

The oil/air mixture, which is fed into the bearing in great quantity, must be able to escape from the rolling bearing, because oil residues can lead to overheating. In order to prevent stagnant oil from forming, discharge channels of an appropriate size must be provided for. If necessary, the oil/air mixture may be extracted by suction (vacuum).

Before bringing into service a spindle lubricated by an oil/air mixture, it is absolutely necessary to ensure that during start-up the rolling bearing is lubricated by a minimum quantity of oil introduced in the course of the mounting process.

Among the lubricating oils that are suitable are alloyed and non-alloyed mineral oils according to standard DIN 51501 and synthetic oils that have a high degree of cleanliness and contain oxidation inhibitors and foam inhibitors.

The reference viscosity according to diagram 5.1 in Chapter 5 (Life time calculation) gives an approximate specification of the required viscosity. But because spindles are often used with a wide range of rotational speeds, many applications will require a compromise. A viscosity of about 7 mm²/s is necessary for spindles used with the maximum speed; spindles used within the medium speed range require a viscosity of about 17 mm²/s.

Oils with a viscosity of < 13 mm²/s should contain EP additives that increase the pressure absorption capacity. If an oil/air lubrication system is used, oil viscosity will have little influence on heating because of the smaller quantity of oil that is involved.

This permits the use of a higher viscosity ratio of $\kappa > 3$ and therefore of viscosities of 32–80 mm²/s at 40 °C, that will help to increase life time.

Oil jet lubrication

Oil jet lubrication is an even safer and an even more complex process. For this type of lubrication, a large amount of oil is supplied, about 100 times the quantity that is used in the oil/air lubrication system. In oil jet lubrication the oil simultaneously serves to dissipate heat. The high churning losses that ensue when this type of lubrication is used must be balanced by a higher driving torque.

For further temperature reduction an interconnected oil recooling system may be used.

For horizontal spindles, the jet velocity of the oil must amount to one quarter of the circumferential velocity of the air vortex that builds up. This velocity is needed so that the oil can break through the vortex. In the case of vertical spindles, however, the application of this type of lubrication is fraught with problems.

With the aid of oil jet lubrication, even higher speed coefficients of over $3 \cdot 10^6$ mm/min can be attained with a minimal rise in temperature. The oils used for this type of lubrication have very low viscosity (about 3 mm²/s at operating temperature).

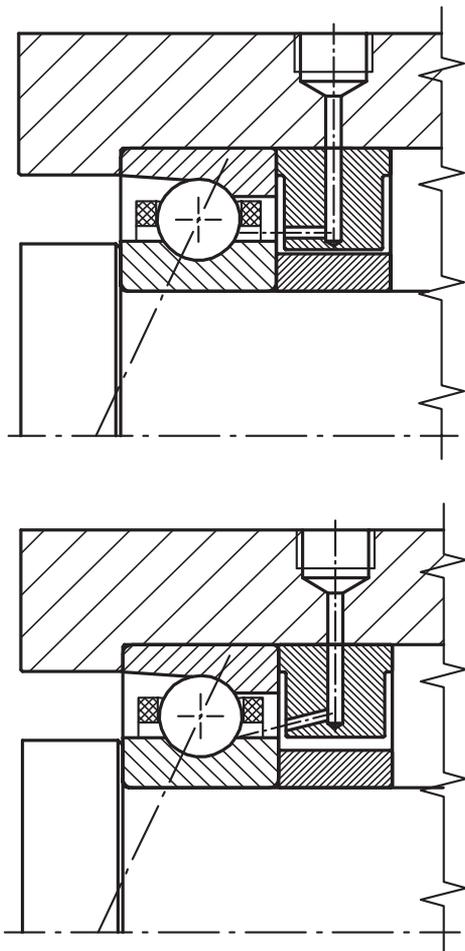

Fig. 7.1: Oil jet lubrication

The complex system of oil/air lubrication is used to achieve very high rotational speeds. If the stress to the rolling bearing is not too high, high precision angular contact ball bearings with smaller diameter rolling elements or rolling elements made of ceramics may also be used. With such rolling elements, even grease lubrication will yield significantly higher speeds when compared to angular contact ball bearings that have larger steel rolling elements.

Table 7.4: Dimensions for lubrication via the outer ring. This type of lubrication is also available for the non-high-velocity executions of angular contact ball bearings.

8. Mounting of High Precision Rolling Bearings

8. Mounting of high precision rolling bearings

Preparing the mounting area

IBC High precision rolling bearings for high precision spindles are manufactured with the greatest care under ultra-clean conditions; they are subjected to intensive tests and are then packed in quality packaging in order to prevent transport damage and contamination.

A clean and dust-free working environment should also be ensured during mounting so as to be able to achieve the best possible running performance. Should fine dust or ultra-fine chipings penetrate the bearing, both the precision and the life time of the high precision rolling bearing will be adversely affected. Abrasive dust is especially aggressive and must be kept away by all means. It is advisable to wholly or partially cover the bearing place with protective foil if a break in the mounting process occurs or if mounting is very time-consuming. Under no circumstances should the bearing be touched with a fluffy cloth. The high precision rolling bearings should also be stored in their original packaging and should be kept safe from moisture or aggressive media.

High precision rolling bearings should generally be kept and stored in a horizontal and not in a vertical position and should be fully supported.

Mounting high precision rolling bearings with unsuitable or unclean tools or mounting aids will considerably affect the working of the high precision rolling bearings and will reduce their capability and life time.

We would like to expressly draw your attention to the fact that IBC will assume no liability for damage that is the result of the mounting instructions not being observed and not being complied with. This also applies to the faulty interpretation or dissemination of the instructions as well as to faulty mounting and maintenance.

Because there are so many different possibilities of mounting a rolling bearing we are unable to treat all options here, especially as such options are also very much specific to the design of the adjacent construction. The following remarks therefore make use

of the fact that in most applications the high precision rolling bearing is first mounted on the shaft and the outer ring of the bearing fitted afterwards.

Preparing the adjacent parts

Apart from checking for dimension and form accuracy, testing of the adjacent parts (housings and shafts) should also include a check for surface roughness of the bearing seats. In the case of tapered seats, the roundness, the taper angle and the straightness of the tapered surface outline should be checked too.

If spacer rings or precision locknuts have been used, these should be checked to see if they run in parallel and are free of burrs and damage. Only faultless mounting parts guarantee the proper functioning of the high precision rolling bearing. If serial mounting is carried out for applications in the upper speed range, it is sensible to divide the tolerances of the housings and shafts into two or three groups. This will make allocating them to bearing sortings easier, a process that helps to achieve interference and clearance fits that are as identical as possible during mounting.

Detailed information on the sortings of IBC high precision rolling bearings are contained in Chapter 4 (Tolerances).

Preparing the high precision rolling bearings

The high precision rolling bearings must be carefully checked before mounting. During this inspection the drawing details need to be compared to the bearing data on the packaging and/or the shrink-wrap foil.

It is most important to prevent dust particles from entering the bearing. A dust-free mounting environment should therefore be ensured, and the protective foil should only be unsealed just before mounting the high precision rolling bearings. It is advisable to wear protective gloves when removing the high precision rolling bearings from the shrink-wrap foil, as hand perspiration may cause corrosion.

High precision rolling bearings are available in the following three executions:

- open, only preserved
- open, greased and identified by the respective suffix (e.g. GS34)
- sealed, greased and with non-contact sealing

If lubrication of the high precision rolling bearings with grease is carried out by the customer, the customer should ensure the grease is compatible with the preservation oil that has been applied. If this is not the case, the bearing needs to be rinsed and then drained. Under no circumstances should a high precision rolling bearing be dried with compressed air. Suitable detergents may be used for rinsing. When using detergents, please observe the instructions for use supplied by the detergent manufacturer as well as the statutory provisions for occupational health and safety and environmental protection.

It should be noted that the choice of grease is of fundamental importance for the working of a high precision rolling bearing with respect to life time, noise level, operating temperature and rotational speed function. After making your choice, lubricate the bearing with the right quantity of suitable bearing grease, while taking into account the free space available and the intended speed.

Information on the right amount of grease suited to each rolling bearing is contained in the grease quantity table 7.2 in Chapter 7 (Lubrication).

During insertion of the grease, particular attention must be paid to greasing the space between the outer ring shoulder and the cage (friction surface). This can be done with a syringe, for instance.

During lubrication, the high precision rolling bearing must be revolved several times so as to distribute the grease as evenly as possible. This will help to shorten the grease distribution run that is carried out afterwards.

You should preserve the remaining bearing surfaces with the grease base oil or with preserving agents that are compatible to the base oil.

Oil lubrication must be used if the limits of the operating conditions for grease lubrication have been exceeded. In order to prevent a potentially detrimental dry start-up in the case of oil-lubricated high precision rolling bearings, it is essential to apply a quantity of the selected oil directly into the high precision rolling bearing before mounting and operation.

Mounting in the right arrangement

In preparation for mounting, the bearing arrangement must be checked against the drawing, and the bearing sets must be arranged accordingly. Because of their unsymmetrical design, angular contact ball bearings may only be loaded in one axial direction. Strict attention must therefore be paid to their direction while mounting angular contact ball bearings or sets of angular contact ball bearings.

In the case of open high precision rolling bearings (see page 8), one outer shoulder has been ground clear for assembly. External loading is via the shoulder that has not been ground clear. An arrow on the outer diameter of the outer ring additionally identifies the load direction, just as in the case of sealed bearings.

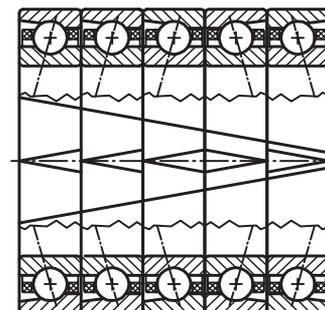

x51-211

Fig. 8.1: Indication of load direction

IBC high precision rolling bearings are in general universally ground. They may be put together in any arrangement during mounting.

In addition to having individual arrow indicators, those sets of high precision rolling bearings that have been put together in our factory in a particular arrangement are marked with a continuous (large) V-marking that spans all the high precision rolling bearings in the set. These sets must be mounted exactly in the direction of the large V-marking and may not be split up. The point of the V-marking designates the mounting direction and the main load direction.

x51-210

Fig. 8.2: Marked bearing set

This also applies to high precision rolling bearings that have been put together to form high precision rolling bearing sets that are balanced with regard to their preload. The possible arrangements for high precision rolling bearings are described in Chapter 2.7 (IBC High precision angular contact ball bearing sets).

Sets of high precision rolling bearings that have been put together in our factory with no particular arrangement are identified by the suffixes DU, TU or QU. These sets are packed together, and each bearing carries only an individual arrow indicator on the outer diameter of the outer ring.

All high precision rolling bearings match each other with regard to their tolerances for bore diameter and outer diameter. This means that they feature the same sorting, i.e., they fall in the same tolerance zone for bore and outer diameter. Detailed information on this process is contained in Chapter 4.3 (Sorting and chamfer dimensions IBC high precision rolling bearings).

All high precision angular contact ball bearings with the tolerances P4A, P2H and P2A are identified by the explicit specification of the mean values D_{gm} and d_{gm} on the external packaging and the foil bag. The bearings are sorted into 2 or 3 groups within the allowed tolerance for bore diameter and outer diameter. This makes it easy to put together bearing sets with the same load bearing characteristics.

Specifying the tolerance of high precision rolling bearings, and taking into account the known tolerances of shafts and housings, enables the user to put together combinations within a series of spindles that each have the same overlap of tolerance zones.

Mounting process

Induction heating of the high precision rolling bearing or heating via heated spacer rings is advisable for inner rings that have interference fits. The inner rings are expanded by this process, which makes mounting easier. If you carry out the heating with induction heating appliances, only the metal rolling bearing components will be heated, whereas the cage and the seals will remain thermally unaffected.

It is absolutely essential to make sure the temperature of high precision rolling bearings that are to be mounted in a heated state does not exceed 80 °C.

When mounting high precision angular contact ball bearings, the displacement force should be brought to bear directly on the ring which is currently to be mounted by means of a suitable tool; the displacement force should not be brought to bear indirectly via the counter ring and therefore via the intermediate rolling elements. Loading the rolling elements with mounting forces should generally be avoided. Start with the ring that has the tightest fit.

When fitting the bearing rings you should ensure that these are fitted tightly to the contact surface in order to avoid settling and misalignment. Such occurrences would lead to premature failure, because the bearings would be operating without preload. If high precision rolling bearings have been fitted to the shoulder in a heated state, the bearing rings must be pushed axially against the shoulder once again after they have been allowed to cool.

Preloading the high precision rolling bearings / tightening torques

Preloading of high precision rolling bearings may be carried out with IBC precision locknuts, with a flange cover that has multiple screws on the pitch circle diameter, or with a central cap screw in the middle of a solid shaft.

Preloading with precision locknuts

If you are preloading high precision rolling bearings with a secure precision locknut with fine thread via the inner rings, the minimum required tightening torque M_D that is needed to overcome the preload may be determined as follows:

$$M_D = 3 \cdot d_{\text{Gewinde}} \cdot F_V \cdot K_{FV} \cdot 10^{-4} \quad [\text{Nm}] \quad [8.1]$$

M_D	min. required tightening torque		[Nm]
d_{Gewinde}	thread diameter of precision locknut		[mm]
F_V	required preload		[N]
K_{FV}	constant of bearing arrangement for F_V of the single bearing = 1 for bearing sets with F_V of preload for the bearing set		
<>	DB	1	<<>> QBC 2
<<>	TBT	1.36	<<<<> PBT 1.71
<<<>	QBT	1.57	<<<<> PBC 2.42

The actual tightening torque is additionally increased by mounting forces due to the effective interference that exists between the bearing rings and the shaft; the quality of the thread and of the affected surfaces have an influence here too. The maximum permissible axial force for high precision rolling bearing rings should be taken into consideration during the process; it may not exceed a lateral contact pressure of about 10 MPa or 10 N/mm² in the area of the raceways, otherwise the raceways may become deformed and the precision locknut may be damaged by excessively high mounting forces. A reduction in mounting forces may be realised if a suitable temperature difference is established between the high precision rolling bearing and the shaft and/or housing.

The following table provides feasible values for the required tightening torque that are meant to serve as a guide:

Bore diameter d mm	Tightening torque			
	718...	719...	70...	72... 73...
6			0.15	
7			0.25	
8			0.32	
9			0.40	
10		0.5	0.80	0.7
12		0.7	1.3	1.0
15		1.0	1.6	1.5
17		1.3	2.2	2.5
20		2	2.9	3.2
25		3	4.0	5.0
30		4	5.6	8
35		6	7.2	11
40		8	9.5	14
45		9	12	17
50	12	11	15	21

150	90	200	275	500
160	115	250	350	590
170	140	310	470	700
180	180	360	600	820
190	240	420	690	950
200	350	520	800	1100

Table 8.1: Tightening torques for high precision angular contact ball bearings

In order to avoid the occurrence of settling, it is advisable first to tighten precision locknuts or cap screws with double the tightening torque, then to unfasten the nuts or screws, and finally to retighten them at the target torque.

Further information on precision locknuts with radial or axial locking and information on how to more precisely calculate the tightening torque is contained in our separate publication **Precision Locknuts TI-I-5020**.

Preloading with flange covers

Clamping the outer rings of the precision rolling bearing to the front side is usually carried out with flange covers that have several screws. With regard to locating bearings, this cover clamps the outer rings of the bearing against a collar in the housing.

Above all in the case of high precision rolling bearings that have a small cross section and belong to production series 718 and 719 (N 19), it may happen that a high, and particularly a one-sided tightening of the screws results in an uneven deformation of the bearing outer ring, as shown in figure 8.3. This may lead to increased radial or axial runout in certain places. Using many small screws is therefore preferable to using only a few large screws. Tightening the screws in an even, controlled and gradual manner will then achieve the desired result.

Deformation of the track above the housing cover due to cap screw

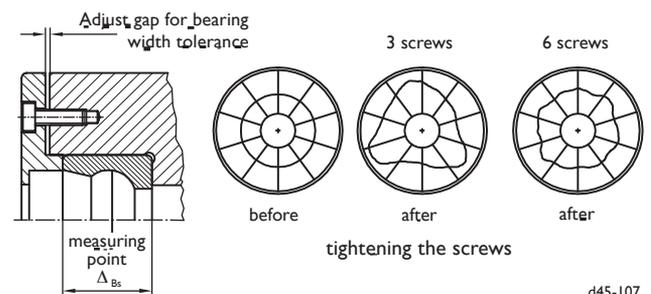

Fig. 8.3: Clamping force distribution at flange covers

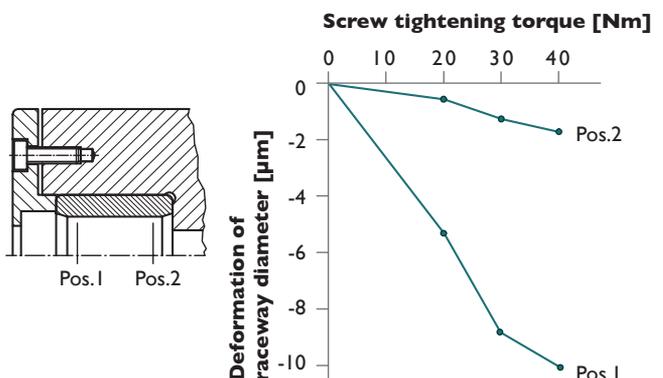

Fig. 8.4: Deformation due to clamping forces

The projection of the cover in relation to the housing (preload gap) should be reduced in the following way to avoid individual cap screws exerting an excessively high clamping force in certain places:

- Bearings with $d < 100$ mm: 0.02 ± 0.01 mm
- Bearings with $d > 100$ mm: 0.03 ± 0.01 mm

When changing rolling bearings, the flange cover or the spacer rings should be readjusted to match the width of the newly inserted rolling bearings. With regard to floating bearings you should make sure that there is no contact with a housing cover, because the cover would restrict the axial expansion of the spindle.

Mounting high precision rolling bearings with tapered bore

IBC high precision cylindrical roller bearings with tapered bore are slid directly on to the tapered part of the shaft. This process expands the inner ring of the high precision cylindrical roller bearing and reduces its bearing clearance δ_r . The endplay is further reduced by the fact that the outer ring is also mounted with a tight fit in the housing.

The bearing clearance is carefully adjusted during the mounting process of the high precision cylindrical roller bearings so as to achieve flawless functioning with the highest possible system accuracy and the longest possible life time.

A lockable precision locknut is used to provide the axial pressure necessary for the adjusting process. The correct axial position of the bearing inner ring is ensured by a sleeve that is ground to measure and is fitted to the shaft between the inner ring of the bearing and the bearing collar.

Determining the sleeve width A requires accurate measuring; the individual steps must also be carried out very meticulously. In principle, there are two different approaches that need to be taken into consideration:

- The inner ring is slid on to the taper. During this process, the enveloping diameter over the roller and/or the raceway diameter is constantly measured until, taking into account the restriction of the outer ring and the way it reduces the bearing clearance, the total remaining bearing clearance corresponds to the required measurement. The remaining axial gap between inner ring and bearing collar then has to be measured with great accuracy, e.g. by feeling one's way with block gauges as shown in figure 8.5. Following this process, the inner ring is released from the tapered seat; a sleeve is ground to the dimension measured and is inserted. Then the assembly of the bearing is completed.

Bild 8.5: Gap measurement

- Carrying out this process in multiple steps is more elaborate and also more conservative. As in the example above, the inner ring is first slid on to the tapered seat on its own, but is not fitted very tightly. The gap between the inner ring of the bearing and the shaft bearing-collar is then measured and the sleeve is made to measure. The enveloping diameter over the roller and/or the raceway diameter are then measured at the mounted inner ring that is clamped against the sleeve. The sleeve is now ground narrower step by step, and the inner ring is remounted after each step. After each step the measurements are recorded and further procedure is decided upon. This approach allows for a high degree of control and reduces subsequent settling.

The multiple-step procedure is described below. The individual steps are numbered from 1 to n ; this is represented in the indexing. Values without index number apply regardless of the relevant step number and do not change during the entire mounting procedure.

Setting the radial clearance or preload δ_r

Cylindrical roller bearings with tapered bore are fitted either with clearance, without clearance or with preload during mounting, depending on the bearing requirements. Different maximum speeds can be attained for each mounting situation; these are listed in table 8.2.

Mounting clearance/preload δ_r	Attainable speed
Single row cylindrical roller bearings	
-5...0 [μm] (preload)	$< 0.75 \cdot n^*$ (grease)
0 [μm] (no clearance)	$0.75 \dots 1.0 \cdot n^*$ (grease)
0...5 [μm] (clearance)	$1.00 \dots 1.1 \cdot n^*$ (grease)
0...5 [μm] (clearance)	$1.00 \cdot n^*$ (oil)
Double row cylindrical roller bearings	
-5...0 [μm]	$< 0.50 \cdot n^*$ (grease)
$2 \cdot 10^{-5} \cdot d_m$ [mm] (clearance)	$0.50 \dots 0.75 \cdot n^*$ (grease)
$4 \cdot 10^{-5} \cdot d_m$ [mm] (clearance)	$0.75 \dots 1.00 \cdot n^*$ (grease)
$1 \cdot 10^{-5} \cdot d_m$ [mm] (clearance)	$1.00 \cdot n^*$ (oil)
*see bearing tables for speed $d_m = (d + D) / 2$	

Table 8.2: Attainable speed for the respective clearance setting

The exact clearance setting is carried out in several steps. First, the interference fit on the outer ring is determined.

$$\Delta_{\text{DAG}} = \Delta_{\text{D}} - \Delta_{\text{DG}} \quad [\mu\text{m}] \quad [8.2]$$

Δ_{DAG}	interference fit outer ring/housing	$[\mu\text{m}]$
Δ_{D}	allowance for bearing outside diameter	$[\mu\text{m}]$
Δ_{DG}	allowance for housing bore	$[\mu\text{m}]$

With Δ_{G} , the restriction of the outer ring is calculated with regard to its mounting.

$$\Delta_{\text{G}} = \Delta_{\text{DAG}} \cdot \frac{D_0}{D} \cdot \frac{1 - (D/D_h)^2}{1 - (D_0/D)^2 \cdot (D/D_h)^2} \quad [\mu\text{m}] \quad [8.3]$$

Δ_{G}	restriction of outer ring	$[\mu\text{m}]$
Δ_{DAG}	interference fit outer ring/housing	$[\mu\text{m}]$
D_0	raceway diameter of outer ring	$[\text{mm}]$
D	outside diameter of outer ring	$[\text{mm}]$
D_h	outside diameter of housing	$[\text{mm}]$

In the first step of the mounting procedure, the inner ring of the high precision cylindrical roller bearing is slid on to the tapered part of the shaft; the result should be a tight but still easily releasable fit. You should then check if the front side of the ring is parallel to the contact surface and/or at right angles with the shaft axis. The distance A between the bearing ring and the contact surface must be accurately measured.

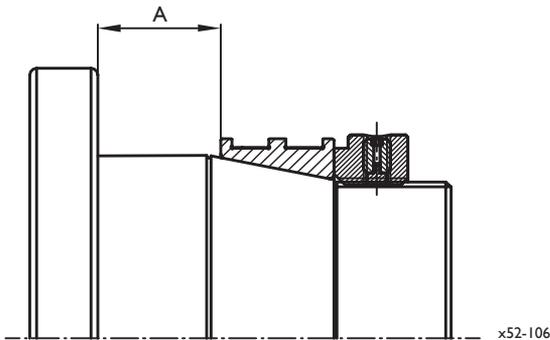

Fig. 8.6: Distance measurement

In the next step, the outer ring of the bearing is mounted by applying very low mounting forces and constantly revolving the ring so as to avoid tilting and the occurrence of scraping marks. In this mounting situation, the existing bearing clearance $\delta_{r,1}$ is then measured. For this measuring process, a dial indicator gauge is affixed to the shaft, and the outer ring of the bearing is moved in the measuring direction of the gauge.

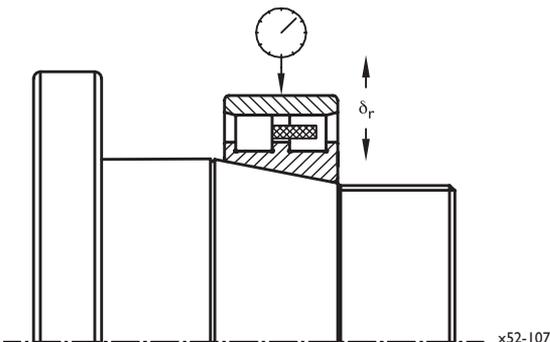

Fig. 8.7: Measuring the bearing clearance

Subtracting the calculated restriction of the outer ring of the bearing Δ_G from the measured radial clearance $\delta_{r,1}$ results in the provisional radial clearance $\delta_{vr,1}$ if the rolling bearing were fully fitted in the housing.

$$\delta_{vr,1} = \delta_{r,1} - \Delta_G \quad [\mu\text{m}] \quad [8.4]$$

$\delta_{vr,1}$	provisional radial clearance after complete mounting in step 1	$[\mu\text{m}]$
$\delta_{r,1}$	measured radial clearance in step 1	$[\mu\text{m}]$
Δ_G	restriction of bearing outer ring	$[\mu\text{m}]$

The actual attainable radial clearance $\delta_{r,n}$ is achieved by grinding a spacer sleeve to the nominal dimension A_n in the last process step n; this dimension guarantees the exact distance to the contact surface of the shaft and parallelism between the contact surface and the inner ring of the bearing. In order accurately to

achieve the required radial clearance δ_r and/or the required preload, this procedure must be carried out in several steps (1, 2, ..., n), because the nominal dimension A_n cannot be determined with adequate accuracy in the first step. The width of the spacer sleeve is recalculated in each subsequent step. The restriction of the shaft is also accounted for during this process, taking into account the hollow shaft ratio.

d_d/d_k	Hollow shaft ratio	[8.5]
d_d	bore of hollow shaft	[mm]
d_k	tapered seat diameter in the taper centre	[mm]

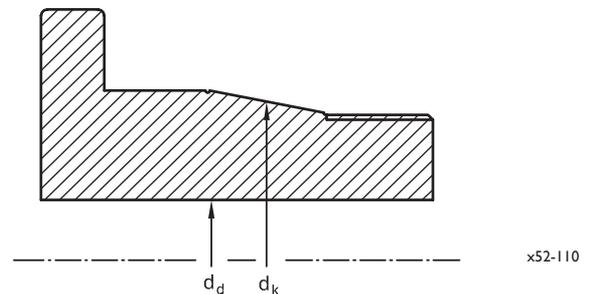

Fig. 8.8: Hollow shaft ratio

While sliding on the inner ring, the radial clearance is reduced by a ratio of 1:12, which also applies to the change in width of the spacer sleeve ($F_k = 12$). However, if the shaft is hollow it will yield elastically, and the proportionality factor F_k will increase.

d_d/d_k	F_k
0.0...0.1	12
0.1...0.2	13
0.2...0.3	14
0.3...0.4	15
0.4...0.5	16
0.5...0.6	17
0.6...0.7	18
0.7...0.8	19
0.8...0.9	20

Table 8.3: Hollow shaft ratio and proportionality factor

The values mentioned serve as an indicator for a ΔT up to 5 K between inner and outer ring. If fitting is carried out for applications that have high temperature fluctuations, please contact our technical service teams.

The following effectively applies to the new dimension of the spacer sleeve width:

$$A_n = A_{n-1} + F_k \cdot (\delta_{r,n} - \delta_{r,n-1}) \quad [\text{mm}] \quad [8.6]$$

n	2, 3, 4, ... process step	
A_n	sleeve width	[mm]
A_1	sleeve width in process step 1	[mm]
F_k	proportionality factor	

The spacer sleeve ground to the dimension A_n is then refitted, and the inner ring of the high precision cylindrical roller bearing is clamped against it so as to force-fit the sleeve. In this condition, the radial clearance $\delta_{r,2}$ is measured.

The measured radial clearance $\delta_{r,2}$ must also be corrected for the restriction of the outer ring of the bearing in accordance with equation 8.4; this results in $\delta_{vr,2}$.

This procedure is conservative, and several steps are needed to attain the required bearing clearance or the required preload. It helps to record each provisional mounting bearing clearance δ_{vr} in relation to the associated spacer sleeve width A in the form of a graph.

This graph will then show the step-by-step approximation to the required bearing clearance; alternatively, it will depict the tendency to achieve the preload if, shortly before reaching the required preload, no more bearing clearance can be measured.

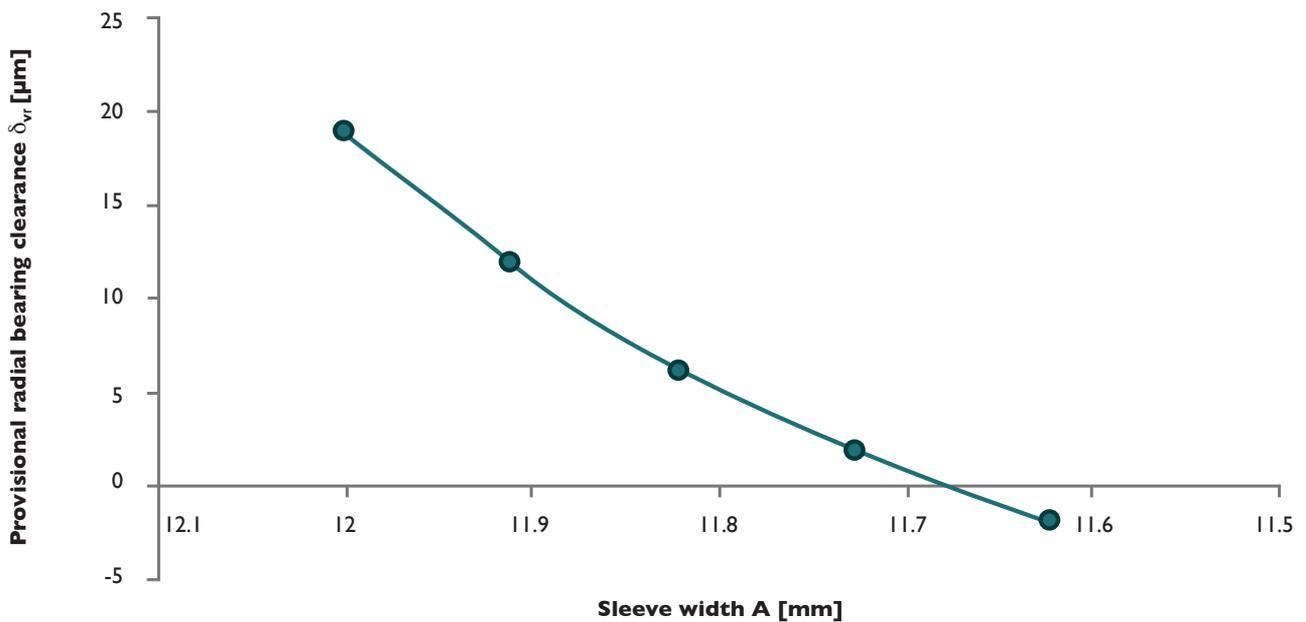

Diagram 8.1: Achieving a preload in 5 steps

9. Materials

9. Materials

Bearing material 100Cr6

Bearing rings and bearing rolling elements are manufactured from vacuum degassed, fine-grained bearing steel 100Cr6 (1.3505). The characteristics of the steel are as follows:

hardness	60...62 HRC 650...710 HV
density	7.83 g/cm ³
specific heat capacity	0.47 kJ/(kg K)
thermal conductivity	46 W/(m K)
electric resistance coefficient	22 μΩ cm
coefficient of thermal expansion	12 · 10 ⁻⁶ /K
Young's modulus	208000 N/mm ²
elastic limit	1370 N/mm ²
tensile strength	1570 N/mm ²
breaking elongation	max. 0.5%
Poisson's ratio	0.3

Heat treatment

The bearing rings made from 100Cr6 are dimension-stable up to a service temperature of 150 °C as standard. For higher temperatures, higher-quality heat treatment is available upon request, provided all the components are designed for these higher operating temperatures.

ChromoTec

IBC high precision rolling bearings from the ChromoTec series with the prefix X have the full load carrying capacity but a very much higher resistance to corrosion.

hardness	58...60 HRC 630...690 HV
density	7.67 g/cm ³
specific heat capacity	0.50 kJ/(kg K)
thermal conductivity	14 W/(m K)
electric resistance coefficient	60 μΩ cm
coefficient of thermal expansion	10 · 10 ⁻⁶ /K
Young's modulus	213000 N/mm ²
elastic limit	2350 N/mm ²
tensile strength	2410 N/mm ²
breaking elongation	3%
Poisson's ratio	0.3

Silicon nitride Si₃N₄

The unique combination of extreme hardness, high mechanical strength, resistance to corrosion and abrasion, low thermal and electric conductivity and a low specific weight make silicon nitride the ideal material for use in rolling bearings. In addition, silicon nitride has a lower adhesion compared to steel and therefore puts less strain on the lubricant.

Even if there is initial stage and progressive damage to a rolling element, the ceramic material will in most cases retain its rolling stability.

hardness	1600 HV
density	3.24 g/cm ³
thermal conductivity	25 W/(m K)
electric resistance coefficient	10 ¹³ Ω cm
coefficient of thermal expansion	3.4 · 10 ⁻⁶ /K
Young's modulus	300000 N/mm ²
elastic limit	1050 N/mm ²
Poisson's ratio	0.27

Steels for IBC rolling bearing rings					
Prefix	Designation	Material No.	USA	Japan	Hardness (HRC)
-	100Cr6	1.3505	SAE52100	SUJ2	60-62
X	X 30 CrMoN 15 I	1.4108	AMS5898		58-60

Table 9.1: Overview of rolling bearing steels

Cage characteristics and features

Bearing cages have a whole range of functions to fulfil in a rolling bearing:

- They keep the rolling elements at a distance, prevent them from touching each other and thereby reduce friction and resulting heat.
- They ensure that the rolling elements are evenly distributed; this guarantees quiet running.
- They guide the rolling elements in the unloaded area of a rolling bearing; this improves the rolling conditions, which in turn prevents detrimental slipping from occurring.

Chemical effects also have to be taken into account. The lubricant and its additives, ageing products that result from lubricant and additives as well as solvents and cooling agents put a strain on the cage materials. That is why widely differing cage materials are available.

Materials for bearing cages

Many cage variations are available, depending on the type of rolling bearing and its size. If bearings are used with high operating temperatures or in problematic operating conditions the use of an alternative type of cage is advisable. Please contact us if you need a special cage for your application.

T	fabric reinforced phenolic resin cage (standard)
P	pocket type nylon cage, PA6.6, fibre-glass reinforced
M	brass cage
PY	PPS cage
K	PEEK cage, fibre-glass reinforced
S	high-grade steel cage
G	PTFE cage

The first two cage options mentioned below are the best suited for use in machine tools. Due to their special characteristics, they cover a broad range of applications.

Fabric reinforced phenolic resin (T)

The low specific weight of this material, a low friction coefficient and its high strength make it suitable for the highest speeds with very low heat generation. The maximum operating temperature is limited to a permanent operation temperature of 100 °C.

Polyamide (P)

Polyamide is also used in a fibre-glass reinforced state and combines low weight with good absorption and good sliding properties. This variant is characterised by a shortened running-in time for grease lubrication.

Brass (M)

Solid cages made of brass are very durable and operate reliably under the most difficult conditions. They are suited to rolling bearings with a higher heat stabilisation that are used with high temperatures.

PPS (Polyphenylene sulfide) (PY)

Cages made of PPS are resistant to most acidic, alkaline and organic solutions. They have a higher strength, toughness and fatigue strength than traditional polyamide cage-materials. They are temperature resistant up to 220 °C.

PEEK (Polyether ether ketone) (K)

This material in a fibre-glass reinforced state is suited to operating temperatures of up to 200 °C. If the temperature range is limited to 150 °C, very high rotational speeds are attainable.

High-grade steel (S)

The outstanding characteristic of this material is its chemical resistance. High-grade steel cages are suited to rolling bearings with a higher heat stabilisation too.

PTFE (Polytetrafluoroethylene) (G)

This synthetic material is chemically and thermally highly resistant and has a very small friction coefficient. This cage material is not suitable for the highest speeds, however. Thermal endurance reaches 250 °C.

Synthetic material cages made of fibre-glass reinforced polyamide PA6.6 are suitable for operating temperatures between -20 °C and +120 °C; it should be noted that the lubricant used has a strong impact on service life. If you are planning to use synthetic lubricating greases and oils with EP additives the chemical resistance of the cage material should be checked in advance. In conditions accompanied by higher temperatures, the life time of a synthetic cage may also be reduced if aged oils are used or if the additives in the oil have aged. Oil change periods should therefore be strictly adhered to. Rolling bearings should not be used with a polyamide cage if they operate near ammonia or Freon acting as cooling agents.

Materials for seals

Sealed high precision angular contact ball bearings have the advantage of being both very reliable and safe. The seal protects the rolling bearing from contamination and thereby extends both the life time of the lubricant and the overall system.

Various materials are used, depending on the operating conditions. The standard material acrylonitrile butadiene caoutchouc (NBR) has absolutely proved its worth in practice. This material has a very good resistance to the following media:

- most mineral oils and lubricating greases based on mineral oils;
- regular-grade petrol, diesel fuel and light fuel oil;
- animal and vegetable oils and fats;
- water, as well as emulsions of water and the above mentioned media.

The application temperature range lies between -40 °C and $+100\text{ °C}$. Higher temperatures of up to 120 °C may be realised for short periods.

For applications that have special requirements with regard to the material of the seal, please contact our department for technical applications. We have used seals made from various alternative materials in the past, e.g. fluoroelastomers (FKM), polyacrylates (ACM) and polytetrafluoroethylene (PTFE).

10. IBC High Precision Rolling Bearings with ATCoat Coating

10. IBC High precision rolling bearings with ATCoat coating

Fig. 10.1: Rolling bearing coated with ATCoat

Fig. 10.2: Cross-section of ATCoat coating

Rolling bearings coated with ATCoat

The material surface of a rolling bearing is becoming more and more important to the overall performance of machines, power units and equipment. However, outside influences very often alter the surface quality of materials or corrode the surface material. A whole range of advantages is achieved by coating the material surface of a rolling bearing.

An ATCoat thin dense chromium coating protects the surface from outside environmental conditions and thereby increases the service life of rolling bearings and the life time of machines and equipment. The advantages of this coating also include energy saving and an efficient use of material. The ATCoat process permits the combination of a tough basic material with a firmly adhering, very thin and accurate chromium coat that is free of cracks. This is why, compared to bearings of the same size, those with an ATCoat coating offer very good resistance to wear and corrosion.

Rolling bearings coated with ATCoat are an alternative to rolling bearings made of corrosion resistant steel. A similar corrosion performance is achieved, especially with regard to the functional surfaces. The coating layer of 2–4 μm has a cone-shaped surface texture and gives an especially good performance in extreme conditions. Especially if used in combination with ceramic rolling elements, ATCoat coating permits a significant increase in speed at lower operating temperatures. Fretting corrosion that may form on floating bearings, a phenomenon that occurs due to the micro displacement of the outer rings of the bearing during thermal expansion or vibration, is also avoided. In many cases this leads to a significantly longer and trouble-free operating of units. Because of the special surface topography, the emergency run properties of the bearings are substantially improved. Should the lubrication system fail for instance, the units are still able to run under part load for a certain period of time; they can also be shut down properly. This means that secondary damage can be limited or avoided altogether. IBC high precision rolling bearings with ATCoat coating are therefore often used in unfavourable lubrication conditions.

Such unfavourable conditions exist for example:

- if lubrication is impossible in a certain environment;
- if lubrication may only be effected with low-viscosity media that do not produce a separative lubrication film;
- if very low rotational speeds occur that do not allow an elastohydrodynamic lubrication film to develop;
- if oscillating movements without achieving a full revolution, and a separative lubrication film cannot be maintained at the reversal points;
- if sliding occurs in unloaded rolling bearings;
- if, during fast accelerations or decelerations, smearing occurs when bearing rolling elements slide due to the force of continuance that is caused by mass inertia in conjunction with an inadequate preload.

Functions of the ATCoat coating

Friction partner	Static friction (dry) [μ_0]	Sliding friction (dry) [μ]
steel/steel	0.25	0.18
steel/ATCoat	0.17	0.15
ATCoat/ATCoat	0.14	0.12

Table 10.1: Friction coefficients

- reduction of friction
- better adhesive strength of the lubrication film
- separation of materials of the same type
- reduction of cold welding caused by adhesion
- reduction of the formation of fretting corrosion
- the sliding properties of a rolling bearing ring with regard to the shaft or the housing are ensured (important for floating bearings)
- outward corrosion protection and extensive chemical resistance to aggressive materials or tribooxidation
- wear protection due to increased hardness of the coating: 72–78 HRC (1300–1400 HV)

Prefix of ATCoat coated rolling bearings

- AC- ATCoat rings
- ACC- ATCoat rings + rolling elements Si_3N_4

Suffix of ATCoat coated rolling bearings

- A11 coated inner and outer ring
- A15 coated inner and outer ring, corrosion resistant rolling elements and cage
- A21 coated inner ring
- A31 coated outer ring

II. Vibration Analysis

11. Vibration analysis

All rolling bearings produce noise during operation. This signal may be accessible and may be monitored, or it may be recorded by technical measuring systems and can then be analysed, depending on the installation situation.

An increase in noise level may be the sign of a bearing defect in the making. A more detailed evaluation is carried out by analysing the impact excitation frequencies. These can then be assigned to specific parts of the rolling bearing if the speed and the bearing geometry are accurately known.

The frequencies can be calculated according to equations 11.1 to 11.4 if there is a revolving inner ring. The table below contains an example of how this is done.

The frequency spectrum of the rolling bearing sound itself is a continuous sound frequency spectrum, with more or less distinct spectral lines. This sound frequency spectrum is analysed with the aid of an envelope analysis which differentiates between the audible sound frequencies of the bearing and the actual impact excitation frequencies. If the frequency spectrum of the envelope shows prominent intensities of impact excitation frequencies, this indicates that a rolling bearing defect has occurred (see table 11.2).

$$RPFO = \frac{n \cdot Z}{120} \cdot \left(1 - \frac{D_w}{D_{pw}} \cdot \cos \alpha \right) \quad [\text{Hz}] \quad [11.1]$$

$$RPFI = \frac{n \cdot Z}{120} \cdot \left(1 + \frac{D_w}{D_{pw}} \cdot \cos \alpha \right) \quad [\text{Hz}] \quad [11.2]$$

$$RRF = \frac{n}{120} \cdot \left(\frac{D_{pw}}{D_w} - \frac{D_w}{D_{pw}} \cdot \cos^2 \alpha \right) \quad [\text{Hz}] \quad [11.3]$$

$$CRF = \frac{n}{120} \cdot \left(1 - \frac{D_w}{D_{pw}} \cdot \cos \alpha \right) \quad [\text{Hz}] \quad [11.4]$$

RPFO	rolling element passing frequency, outer ring	[Hz]
RPFI	rolling element passing frequency, inner ring	[Hz]
RRF	rolling element rotational frequency	[Hz]
CRF	cage rotational frequency	[Hz]
n	operating speed of inner ring	[min ⁻¹]
Z	number of rolling elements	
D _w	diameter of rolling elements	[mm]
D _{pw}	reference diameter	[mm]
α	contact angle	[°]

	Damage frequency CB 7207.C.T.P4A.UL Input	
contact angle	15	α [°]
operating speed	1000	n [min ⁻¹]
number of rolling elements	9	Z [pieces]
diameter of rolling elements	11.112	D _w [mm]
reference diameter	53.5	D _{pw} [mm]
	Output in Hz	Reference number
rotational frequency (n/60)	16.667	1.0000
cage (CRF)	6.6025	0.3961
outer ring (RPFO)	59.422	3.5653
inner ring (RPFI)	90.578	5.4347
rolling element (RRF)	76.782	4.6069

Table 11.1: Example of a worksheet for rolling bearing frequencies

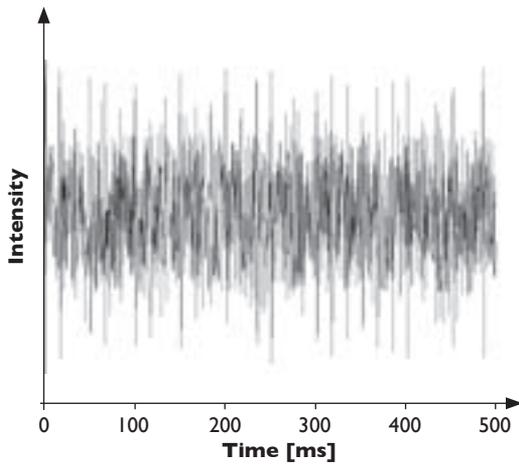

Fig. 11.1: Recurring pulses may indicate that the rolling bearing has been damaged

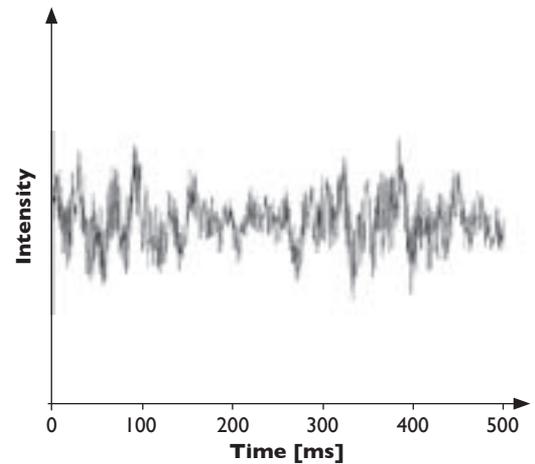

Fig. 11.2: Structureless noise of a faultless rolling bearing

Cause	Dominant frequency	Measuring direction of vibration	Note
damage to rolling element	RRF	radial	Impact excitation from damaged rolling elements occurs together with their rotational frequency. The cage rotational frequency is also noticeable at the edge. Harmonics also occur to a high degree.
damage to cage	RRF, CRF	radial, axial	A damaged cage only seldom leads to an unambiguous signal. Frequencies occurring are often variable. RRF may occur out of alignment.
damage to rings	RPFO, RPF1	radial	Depending on the location and the position of the damage, RPFO or RPF1 may be more or less clearly identified. A developing signal intensity is often distinguishable over time. A migrating of the damage to the rolling elements may be observed on the basis of RRF.
lubrication	various	radial, axial	Faulty lubrication can lead to a high-frequency, wide-band and comparatively strong signal. Re-lubricating will reduce the signal. Monitor the signal strength of the bearing for a renewed increase.
unbalance of rotor	$n/60$	radial	The rotational frequency of the rotor is clearly distinguishable in the signal. It is a distinctive point of reference in the frequency spectrum.
misalignment	$n/60, n/120$	radial, axial	A signal due to misalignment occurs for full or half passing frequency, this is however not very meaningful for determining the defect. A different kind of inspection is therefore required.
excessive clearance	$n/120$	radial, axial	An increased signal occurs for half rotational frequency but also often for full rotational frequency. The signal is not very characteristic, however. An additional inspection of the bearing with regard to clearance is required.

Table 11.2: Cause and associated frequency

Checklist for Bearing Specifications

Operating conditions:

Axial load: _____ N

Radial load: _____ N

Type of load: static
 dynamic

Speed: _____ min⁻¹

Load application: rotating inner ring
_____ h

rotating outer ring
_____ h

load rotates with IR

load rotates with OR

load direction fixed

Fitting position: vertical

horizontal

Temperature: _____ °C

Ambient medium: _____

Lubrication: _____

Life time until now: _____

Designated life time: _____

Other (bearing clearance, preload, etc.)

Adjacent parts:

Shaft:

Diameter: _____ mm

Tolerance: _____

Bore:

Diameter: _____ mm

Tolerance: _____

Bearing used until now:

Designation: _____

Manufacturer: _____

Annual requirement: _____ units

Purchased from: directly from manufacturer _____

through a dealer _____

Company: _____

Contact person: _____

Telephone: _____
